All indices given by Lamont *et al.* are included with the exception of Gleason's index whose value is directly related to population density. *S* is the total no. of species in the sample, *p_i* the relative frequency of the *i*th most frequently occurring species, $\log \bar{p} = (\sum \log p_i)/S$, *R*₁ and *R*₂ the quartiles of the frequency distribution. The logarithms are taken to base *e*. The *Q*-statistic is derived directly from the data and from the parameters of three fitted models.

* The log-series diversity index α is not directly comparable with other indices for the heathland site as it is calculated from the species numerical abundances not their IVI importance values.

† Bracketed figures are obtained by omitting single rarest species. This operation has a negligible effect on other indices.

Fig. 1 Importance value index plotted against species sequence for 172 species from Western Australian heathland site¹. Continuous and broken curves are for fitted log-normal and gamma distributions respectively.

LAMONT ET AL. REPLY—Use of the best-fit ('characteristic') slope of the importance-value curve as a measure of diversity has intuitive appeal. The problem in species rich samples, however, is that nonlinear models generally fit the data better than linear ones. In view of this, use of the variance might prove an acceptable alternative. We maintain that both these measures are indices of evenness and not of total diversity, such as Shannon's which confounds both evenness and richness (Fig. 1).

Comparison of our heathland data against results for Preston's classic curve-fitting procedure for the log-normal distribution^{1,2}, using the χ^2 test favoured by Kempton and Taylor³, confirms our previous conclusion of their dissimilarity⁴. Using the more recently devised methods

Fig. 1 The relationship between evenness and total diversity: one community (for example representing a McArthur distribution) has half the slope (twice the evenness in terms of number of species per unit importance), but only half the number of species (half the richness) as the other (for example representing a log-series distribution). Only when these figures are multiplied do we have an indication of total diversity—in this case they should be the same.

of estimating log-normal and gamma parameters, adopted by Kempton and Taylor, we now see that the difference becomes nonsignificant. Because lumping may mask variation in the original data, particularly in the dominant-species region (a limitation of the variance approach to evenness) it is desirable to compare the log-normal curve against the observed curve. In our original paper⁴, the scaling was fixed so the χ^2 values for the fitted curves gave some indication of their relative goodness of fit, but the significance levels should be ignored. We relied, however, on the more appropriate one-sample, Kolmogorov-Smirnov test⁵. The observed and expected importances for the log-normal fit by Kempton and Taylor above were significantly different at the 0.1% level,

and for the gamma fit at the 5% level. The latter is worse than the log-series, but better than the (linear) exponential⁴.

We agree with Kempton and Taylor that the gamma index (S/σ^2) is the best variance measure of evenness, even though it does not fit all data and is not synonymous with the best fit slope. It should not be confused with the quartile index which is an inferior slope measure³. The exponential curve remains the best measure of slope, though removal of the dominant species is sometimes required to meet the requirements of the Kolmogorov-Smirnov test, with minimal change in slope. We now consider removal of up to 10% from each tail (our original characteristic slope⁴), let alone 25% (quartile), is unwarranted.

We made it clear⁴ that William's index, based only on number of individuals (largely a function of life form), for the Malaysian rain forest was much higher than for the Western Australian heathland. We are therefore not surprised that data we considered of little relevance to community diversity (except in providing species richness/number of individuals), and incompatible with ours, continues to show a higher diversity when expressed in terms of other indices. In addition, we point out that the rain forest site was not physiographically uniform⁶, it is difficult to identify communities in this rain forest anyway⁷, the method of survey ensured high evenness: specimens had to be tall trees exceeding 30 cm in diameter but no reference was made to their size, and the sample was nearly 450 times the area of ours and 20 times its height. Had small plants been included and more acceptable measures of importance been used it is certain that the vast increase in range of values would have greatly reduced evenness. Such inclusions would no doubt have increased the slope of the species-area curve of the rain forest above that of the heathland, but the extensive experience of one of us in related Dipterocarp rain forests indicates that ten 50 m² samples which contained 150 species, let alone 172, would be most unlikely.

Renewable energy sources and storage

LEICESTER, NEWMAN AND WRIGHT¹ claim to have invalidated Ryle's² hypothesis that windpower could make a substantial and economical contribution to Britain's electricity supply, once short-term (150-h) thermal storage is provided at places of end-use. The counter-argument of Leicester *et al.*¹ seems to be based on two principal observations. (1) Plots of average heat demand against mean windpower output, which show that the standard deviation of windpower output is large and decreases only slowly with storage capacity. And (2), their "extreme example" for which the mean wind energy available over the period 1 February–31 March 1975 was about 54% of the long-term average wind energy. Unfortunately, neither of these observations provides a test of Ryle's hypothesis.

Observation (1) confirms the well-known fact that windpower is very variable. However, since the probability distribution of windpower is highly skewed in general, it is not particularly useful to quote standard deviations. More importantly, the scatter diagrams do not necessarily provide useful information on the crucial problem of storage content. The proposition by Leicester *et al.* that their interpretation of Ryle's thesis implies that the points in their Fig. 2b should be grouped around the straight line through the origin of slope unity, is false. The grouping is sufficient but not necessary. Because windpower is proportional to the cube of windspeed, the store can be filled quickly but will be emptied slowly.

A simple example brings out this inadequacy of the scatter diagrams. If the daily output is constant at 1 unit, which seems to be a reasonable first approximation to the data presented, then 11 days' successive input of $\frac{1}{2}$ unit followed by a day with an input of 6 units keeps the store non-empty at all times, given that it was initially full. Yet the running 6-day average inputs are $\frac{1}{2}$ for half the time and $1\frac{1}{2}$ for the rest, giving a wide scatter.

In contrast to their scatter diagram (Fig. 2) which is not helpful, quantitative information on windpower reliability is obtained from plots of power availability or capacity factor expressed as a function of storage capacity^{3–5}.

Observation (2) merely reiterates the well-recognised point that windpower plus short-term storage alone cannot satisfy power demand with a probability of unity. However, Ryle² does not assume that there are no conventional sources of power feeding the grid. We suggest that some of the real questions of quantitative significance raised by Ryle's work are as follows. First, what is the probability of low-wind periods of a given length? Second, how much conventional (that is,

non-renewable) baseload, intermediate load and peakload capacity must be retained in a grid fed by windpower to ensure that low-wind periods can be covered with a probability close to unity? Third, what are the additional economic costs and benefits of such a hybrid grid? For example, the costs of extra start-ups of conventional power plants during low wind periods and the losses of unutilised windpower when storages are full; the benefit in replacing new or retired fossil-fuel and nuclear plants with windpower or other renewable sources of energy; fuel-saving benefits when de-controlled as well as controlled prices are considered for fossil fuels. Finally, by how much are the answers to the second and third questions changed when a more flexible method of load switching and pricing is introduced? Such an automatic rationing system is technically feasible and could mean that instead of freezing over the period 7–16 February 1975, CEBG all-electric householders would have experienced simply a fall in home temperatures of (say) 5°C over the longer period 2–16 February. For the case of central or substation storage, we have found that a user strategy in which part of the windpower output contributes to the immediate demand and part is proportional to the fraction of energy in storage, yields a substantial increase in the availability of windpower, compared with the strategy of simply following demand (M.D. and K. Malafant, in preparation).

Leicester *et al.*¹ do not attempt to modify user demand, nor consider probabilities of extreme events, nor hybrid systems, nor economics of any kind. Their interpretation of their scatter diagrams is based on a false proposition. It is, therefore, difficult to understand the basis of their assertion that Ryle is "probably incorrect" on relative economics and that "sufficient work has already been done to demonstrate that 150-h storage is quite inadequate to smooth the output of wind generators".

We thank Jeff Wood, Sue Carpenter and Brian Martin for helpful discussions.

LEICESTER ET AL. REPLY—Since our earlier work we have extended our analysis to determine the amount of storage that would have been needed to match heating demand to windpower output throughout the period 1 October 1974 to 31 March 1975, assuming an energy

balance over the period as a whole. We have done this by calculating and then adding together the maximum cumulative surplus and deficit of windpower output relative to heating consumption over the 6 months. The storage requirement turns out to be 1,124 h, thus substantiating our contention that 150-h storage is quite insufficient.

We have also calculated the normalised averages of heating demand and windpower output for 1,124-h periods within the 6 months and find that the former extend from 0.9 to 1.04 and the latter from 0.4 to 1.73. The standard deviation of the heating demand is now 0.028 and that of the wind energy is 0.394, which are about half the values with 150-h storage. Although these results support Diesendorf and Westcott's argument that zero scatter is not a necessary condition of sufficiency of storage, they do show that with sufficient storage the scatter is very much smaller than for 150-h storage as shown in our Fig. 2b.

Diesendorf and Westcott raise a number of other questions which, we agree, are relevant in a wider context. However, there is clearly a difference in view between us on what Ryle has proposed. Our understanding of his concept is that, he contends that, by controlling the electrical input to storage for space heating and hot water supply by remote switching in accordance with the availability of windpower output, the heating demand can be fully and reliably satisfied without recourse to supplies from other generating plant. We believe that our analysis shows conclusively that 150-h storage is not sufficient to support Ryle's contention, but this does not mean that the use of storage with renewable energy sources is unimportant. Indeed, while it was not the purpose of our article to do more than examine the storage proposition as formulated by Ryle, we are nevertheless continuing to study the question of integrating large amounts of windpower into the CEBG's system and this will include consideration of questions (1), (2) and (3) posed by Diesendorf and Westcott.

With regard to their fourth question, a policy of selective rationing of electricity for heating is not feasible since consumers could not be denied freedom to resort to electrical supplementary heating at times of storage deficiency in cold spells. Such use would inevitably occur and the consequent peak load on the supply system could be close to what it would have been without windpower generation with the result that the latter would have minimal firm capacity.

Understanding speciation

Godfrey M. Hewitt

Modes of Speciation. By M. J. D. White. Pp.455. (Freeman: Reading, 1978.) £18.50.

SPECIATION involves the splitting of a single evolutionary lineage into two or more genetically independent ones. This process of cladogenesis is one of the twin axes of organic evolution, the other being the process of anagenesis which involves the phyletic change of an evolutionary lineage through geological time. In the *Origin of Species by Means of Natural Selection* (1859) Charles Darwin dealt with both of these fundamental processes, although perhaps understandably at that time he was more concerned with incontrovertibly establishing anagenesis ("descent with modifications") than with discussing the mechanisms of cladogenesis ("the origin of species"). Nevertheless in chapter four a few short passages reveal that he considered both disruptive selection to fit distinct niches and geographic isolation on islands as important mechanisms of evolutionary divergence. In fact Alfred Russell Wallace (1901) considered the process of speciation more closely.

The 'Neo-Darwinian Synthesis' of evolutionary theory was made some thirty years ago and continued to emphasise phyletic change. However, geographical isolation was now considered to be of prime importance in speciation and by some as a necessary pre-condition. Consequently, nearly all books on evolution devote only a chapter or so to cladogenesis. This remains so in the recent stimulating text *Evolution* by Dobzhansky, Ayala, Stebbins and Valentine (1977), and Verne Grant's thoughtfully integrated *Organismic Evolution* (1977) devotes one of eight major sections to speciation. Ernst Mayr gives the topic major prominence in his *Populations, Species and Evolution* (1970), but this book considers only animals and like its parent volume *Animal Species and Evolution* (1963) vigorously favours geographical isolation. Grant's *Plant Speciation* (1971) is the only book to deal specifically with cladogenesis, but as the title indicates it is restricted to plants.

Against this background Michael White has decided to produce a "comparative study of speciation in relation to the population structure and genetic

architecture of living organisms". He deals with both animals and plants and considers a wide range of possible modes of speciation. This book may thus be considered as the first comprehensive treatment of the origin of species.

It is also a most timely publication. There has been an accumulation of pertinent studies over the past twenty years, the most striking discovery being the considerable level of genetic variation revealed by gel electrophoresis of proteins. And there have also been substantial advances in the less well publicised fields of chromosome variation and behavioural isolation. Some of these investigations have raised nagging doubts as to whether an extended period of geographical isolation is a necessary prerequisite for the production of genetic isolation and speciation. This growing concern can be sensed in the later texts referred to above and in a number of recent papers and reviews. As White himself recognises, "the time therefore seems ripe for a reconsideration of the whole question of the mechanisms of speciation . . . It is probable that a number of modes of speciation exist, and that the simple antithesis of allopatric and sympatric modes is a false one, since most of these involve a geographic component of some kind".

White admits in the preface that "the organisation of the book presented some major difficulties. Many controversial topics could have been discussed equally well in any of several chapters". Nevertheless, the structure which he has chosen to deal with this immense subject proves a successful vehicle to convey his message. Furthermore, the book is very readable, usefully illustrated and well produced. It contains seventy-six pages of references alone and though most of them are recent, it provides a valuable link with the older literature.

Chapter one is a lively introduction; in it he is at pains to convince doubters that species and speciation are identifiable concepts and worthy of study. This leads to a consideration of isolating mechanisms, the genetic processes involved in evolution and the type of data required for a full study of each case of speciation. He is unhappy with previous classifications of models of

speciation and proposes seven models that span the range from pure allopatry to pure sympatry. These models are then dealt with in detail in later chapters, as are polyploidy and parthenogenesis.

Before this exposition the stage is set by a chapter on the genic structure of species and a chapter on chromosomal differences between species. The former provides a balanced and pertinent account of the mushrooming data on electrophoretically detected allelic differences and the questions raised by this. Perhaps the most important conclusion is that related species may differ very little in their allozymic constitution. The massive chapter on chromosomal differences is reminiscent of the author's encyclopaedic work *Animal Cytology and Evolution* (1973). With such a vast array of information at his command the initial heading of sections certainly aids the reader, and it is a pity that this is discontinued after the section on *Drosophila*. It is his expressed intention to advocate a much larger role for chromosomal rearrangements in speciation than in earlier texts and he certainly hammers home the portentous fact that very few, if any, closely related species are chromosomally identical. From this he concludes that these chromosome changes cause speciation, but does not present fully an argument to justify this. Nevertheless, the association of chromosomal difference with speciation requires an explanation.

The allopatric models of speciation in which genetic isolation is acquired under complete geographical isolation are examined in chapter four. Several clear cases are discussed and a number previously claimed as examples are critically reassessed. These necessarily include the Galapagos Islands, the Hawaiian *Drosophilidae*, the land snails of the Society Islands and Caribbean and the species flocks of ancient lakes, as well as lesser known work in frogs, locusts and lemmings. Character displacement and reinforcement of species-isolating mechanisms are briefly treated at the end of the chapter; these contested subjects are perhaps worthy of more fundamental consideration.

Clinal and area-effect models are considered next. These propose the segregation of distinct species out of

geographical races that are spatially continuous. The thrust of this chapter depends firstly on Bryan Clarke's (1968) model for which there is suggestive evidence and secondly on the reinforcement of hybrid zones over which White is perhaps prematurely enthusiastic. However, these models are as yet relatively under-explored, and he is right to promote interest in them.

The chromosomal modes of speciation are considered seriously in the sixth chapter to account for the widespread occurrence of karyotypic differences between sister species. Harlan Lewis' pioneer work with *Clarkia* argues powerfully for saltational speciation as a form of microallopatry involving hybrid chromosomal sterility, and the bulk of the chapter describes cases that White considers to support his own stasipatric model. This latter is essentially a clinal model driven by hybrid chromosomal sterility. Some authors will possibly be surprised to find their data so interpreted, particularly when they themselves have invoked geographical isolation. Both this chapter and the last are concerned with what Murray (1972) has called parapatric speciation and further investigation will clarify our concepts.

The chapter on sympatric models of speciation is well written and the concepts are readily grasped. This is a result in part at least of the resurgence of interest in the early 1960's through studies such as those of Maynard-Smith and Thoday and Gibson on disruptive selection. The strength of the case rests with the evidence from host-specific insects, particularly that of Bush (1974) on *Rhagoletis*. White makes a good argument for sympatric speciation on small oceanic islands with many species and also for allochronic speciation.

Following a neat review of speciation by polyploidy, White considers it to be fairly insignificant in most organisms, excepting certain groups of plants such as ferns and grasses where it may perhaps have inhibited speciation by other methods.

Chapter nine extends the species concept to include isolation by asexual reproduction and we are treated to an exposition of one of White's pet subjects. He demonstrates the hybrid origin of many thelytokous species, but one wonders if heterosis of the hybrid is absolutely necessary to explain their origin. In the invertebrates at least thelytoky is a sporadic development and he emphasises that though much has been written about the vast agamic complexes in plants there are very few of these. His consideration of the currently engaging question, "What biological use is sex?" is not complete but certainly points the way, and he advocates examination of the genetic architecture of thelytokous species and

their bisexual relatives as presently more necessary than model building.

I found the last chapter (Conclusions) the most enjoyable. It contains all sorts of evidence, concepts, ideas and questions that arise from the preceding survey. One might argue that some of the points on behaviour, sex, hybridisation and reinforcement should have been considered before the models, but one must break into the cycle of scientific enquiry somewhere and this approach is certainly realistic and stimulating.

A comprehensive study of speciation

Automated chess

The Machine Plays Chess. By A. G. Bell. Pp. 114. (Pergamon: Oxford, New York and Sydney, 1978.) Hardback £5; paperback £3.

It is one of the rarer pleasures of a book reviewer to receive a text which both entertains and informs him simultaneously. This book was the source of one such pleasure.

The text commences with an excellent commentary on the principal stages in the historical development of chess automation, going back through the pre-electronic "paper machines" of the early twentieth century, the ideas of Babbage and Turing, and the famous "Turk" pseudo-automaton of the eighteenth century.

The main part of the book deals with the situation in recent years, and

requires the use of a wide range of biological studies. This text will no doubt provoke specialists in many areas, but there are so few people capable of giving us such a fine prospect. This personal view should be read by every serious biologist, for Michael White has succeeded in producing a most readable, comprehensive and stimulating thrust towards understanding speciation—may it bear fruit.

Godfrey M. Hewitt is Reader in Genetics at the School of Biological Sciences, University of East Anglia, Norwich, UK.

succeeds admirably in communicating an insight into the 'thought processes' of computer programs (and their authors). The selection of example games clearly shows the super-human capabilities of the computer in tactical calculation, and with equal clarity exposes the perpetual undercurrent of planlessness which is the trademark of all automata. A sensible appendix supplements the main text with a simple explanation of the special techniques used in move selection and evaluation.

This is a book which can be recommended as almost essential for those interested in machine intelligence, would be entertaining for chessplayers of all standards, and provides an excellent introduction for those with experience of neither.

N. J. Holloway

N. J. Holloway is Lecturer at the Astronomy Centre, University of Sussex, UK.

Neural mechanisms of memory

Elements of the Behavioural Code. By Francis V. DeFeudis and P.A.F. DeFeudis. Pp. 397. (Academic; New York, London and San Francisco, 1977.) £15; \$29.35.

WHAT progress is being made toward the understanding of neural mechanisms of memory in terms of biochemical and anatomical changes in the brain? This seems to be the overall problem set by DeFeudis and DeFeudis. Their main effort in this book has been devoted to surveying changes observed in the nervous system as a consequence of exposing experimental animals to enriched or impoverished environments, or giving them training, or using physiological and/or pharmacological techniques to alter the functional load imposed on the nervous system. Proceeding generally from broader to finer effects,

the authors describe changes found in the gross anatomy of the nervous system, in cellular and subcellular morphology, in neural macromolecules, in energy metabolism, and in presumed neurotransmitters and some other small molecules. This survey is based on an impressive list of over 1800 references, about three-fifths of them from the 1970s and including many citations from 1976 when the manuscript was completed. Following the 89-page reference list are a 29-page subject index and a 25-page author index. The selection and compilation of this material and rendering it accessible through the detailed indexes are sure to be of great help to investigators and advanced students in all the disciplines that are contributing to the study of the biology of memory.

Given the magnitude of the task, it is understandable that DeFeudis and DeFeudis have been somewhat less successful in describing and interpreting the varied and rapidly accumulating material of this field than they

AIMS AND SCOPE

This international journal will deal with the design, methods and operational aspects of prospective follow-up studies with emphasis on controlled clinical trials. Appealing to those in medicine, biostatistics, epidemiology, computer science, management science, behavioral science and bioethics, the journal will publish papers in the following subject areas:

Unusual design features of specific studies which may be applicable to other studies
• Organizational structures which facilitate multicenter investigations • General or specific design and operating features for data processing systems used for maintaining data base for long-term follow-up studies • Methods for assessing patient compliance in ongoing trials • Design principles for forms and other data collection techniques for long-term follow-up studies • Quality assurance procedures for error detection in the data generation and processing procedures in long-term follow-up studies • Methods of sample size calculation designed for long-term trials • Historical review of clinical trials or of study trials given in a specific area of investigation • Methods of monitoring trial data for evidence of adverse or beneficial treatment effects • Statistical methods designed to deal with methodological problems • Medical, legal and ethical issues in the conduct of prospective follow-up studies • Management of multicenter investigations.

52 VANDERBILT AVE. NEW YORK, N.Y. 10017

Circle No. 13 on Reader Enquiry Card.

At Last! A Reliable Incubator Under \$100 Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and
FASEB Meetings

With this Modular Incubator Chamber you no longer have to worry about the inherent variability (due to CO₂, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators. Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv-resistant polycarbonate.

Multi-purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only \$95*. To order or for further information phone or write Billups-Rothenberg, Inc., Dept. N-1, P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

ASA Monograph**Sex and Age as Principles of Social Differentiation**

edited by J. S. La Fontaine

September/October 1978, viii + 188pp., £6.20/\$12.75 0.12.433050.9

This book presents a collection of papers designed to focus attention on a neglected topic: the nature of ascriptive roles. Two of the most common ways of establishing social differentiation are by age and by sex, and although the two principles have usually been discussed separately, they are similar since each is a cultural transformation of a natural process of human physiology — ageing, and reproduction. Very often, too, the principles are found in conjunction, and the relationship between the sexes may depend on the existence of a ritualised distinction between mature and immature.

Developmental Dysphasia

edited by Maria A. Wyke

September/October 1978, xli + 180pp., £7.80/\$16.15 0.12.766950.7

Developmental dysphasia has attracted considerable attention for a number of years. The problem has engaged the interest of scientists from very different fields, and many attempts have been made to unravel the essential nature of the disability. For a long time the deficits of children with developmental dysphasia had been merely observed and recorded, but lately there has been an increasing number of investigations which have viewed developmental dysphasia in the light of more rigorous experimental procedures. This book presents an up to date account of the work carried out in the field of developmental dysphasia.

Adverse Response to Intravenous Drugs

edited by J. Watkins and A. Milford Ward

September/October 1978, x + 188pp., £8.20/\$17.00 0.12.737850.2*

In spite of its numerous advantages to the clinician, the intravenous route for drug administration presents certain difficulties of adverse response, with implications in many areas of medicine, notably in anaesthetics and blood plasma-substitute technology. For the most part the reactions are histaminoid or anaphylactoid, but it is clear that genetic, physiological and psychological factors also play a part in generating the adverse response. The precise nature of this response is, however, far from clear, and this book will help to throw light on the issue. Most of the papers in this volume were first presented at a Symposium held at Sheffield University Medical School in June 1977.

[Published in New York by Grune & Stratton Inc. ISBN 0.8080.1098.1]

Inorganic Polymers

N. H. Ray

September/October 1978, xli + 174pp., £8.40/\$17.35 0.12.583550.7

There is a need to develop new inorganic materials to supplement and replace synthetic organic polymers which are derived from the diminishing fossil carbon resources of the earth. With this in mind, this book provides a comprehensive survey of inorganic polymers from the viewpoint of a materials scientist, with particular emphasis on their structures and properties and the relationships between the two. In doing so it brings together data from a variety of sources not often consulted by polymer scientists, such as mineralogy, glass technology and synthetic chemistry.

ISAM '77**Proceedings of the Second International Symposium of Ambulatory Monitoring**

edited by F. D. Stott, E. B. Raftery, P. Sleight and L. Goulding

September/October 1978, xviii + 332pp., £10.50/\$21.75 0.12.672350.8

Ambulatory monitoring deals with the collection and analysis of physiological data from subjects who are free to carry out normal activities, whilst the data is being recorded. In principle, it is not a new technique; electro-cardiographic monitoring, using portable equipment, has been employed for nearly twenty years as a tool in clinical cardiology and for research. At the first symposium, ISAM '75, this was the major field of interest represented, but ambulatory monitoring of blood pressure was also an important topic. Both these fields are well represented again in this, the 2nd Symposium, but in addition other varied applications in electro-encephalography and in physical rehabilitation medicine have increased in importance.

Language, Thought and Culture: Advances in the Study of Cognition**The Cultural Definition of Political Response**

Lineal Destiny Among the Luo

David Parkin

September/October 1978, xxli + 348pp., £14.80/\$30.65 0.12.545650.6

Cultural change is not just a straightforward response to external pressures: the culture itself, as a powerful and autonomous system of ideas, plays a large part in shaping people's internal adaptation to new circumstances. Recent far-reaching changes — educational expansion, increasing wage dependency, population growth and urban unemployment — have all had their impact on the populations of Africa, but underlying cultural differences have persisted throughout. It would be misleading, therefore, to think of ethnicity as a mere 'false consciousness', without any bearing on the destiny of a people. The Luo of Kenya, who are the main subject of this investigation into the nature of cultural change and its semantic aspects, are no exception to the rule.

The Environmental History of the Near and Middle East

Since the Last Ice Age

edited by William C. Brice

September/October 1978, xx + 364pp., £16.00/\$33.15 0.12.133850.9

The landscapes between the Mediterranean and the Valley of the Indus have undergone many alterations since the climax of the last Ice Age, some 20,000 years ago: lakes have filled and dried out, rivers have shifted their courses and deserts created, forests have receded and advanced. These changes, which manifestly affected the inhabitants and their ways of life, are of particular historical moment as they coincided with crucial early experiments in the arts of agriculture and domestication; of irrigation, architecture, metallurgy, commerce, and the building of cities. This is a collection of recent observations on the nature and extent of these changes of environment, by scholars from eight countries and several disciplines.

Action, Gesture and Symbol: The Emergence of Language

edited by Andrew Lock

October/November 1978, xiv + 588pp., £22.00/\$45.50 0.12.454050.3

How does a child move from the early, pre-speech types of communication to a fully-developed use of language? This collection of essays puts the challenge: is there a developmental continuity between preverbal and verbal levels of communication; is the latter predicated on the former? The book suggests that the infant's early interaction with the social milieu lays the foundation for language, and pursues this view in five sections, each exploring a particular facet of the topic. Theoretical problems regarding the continuity of communicative systems are posed, and the evolutionary question, early mother-infant interaction, and the transition from gesture into language symbols are explored. Finally, the role of social processes in the creation of linguistic abilities is considered.

The Endocrine Hypothalamus

edited by S. L. Jeffcoate and J. S. M. Hutchinson

October/November 1978, xviii + 546pp., £23.00/\$47.50 0.12.382150.9

Recent research on the hypothalamus has led to several important endocrinal discoveries and redefinitions, particularly concerning the chemistry and functions of the hormonal peptides. This book is a much-needed, balanced critical review of the subject, written by an international panel of authors, all of whom are actively engaged in their particular subject. The first half of the text deals with general aspects of the endocrine hypothalamus; anatomy, hormones, methods of investigation and control mechanism. This is followed by more detailed chapters on the separate hypophysiotrophic functions; control of thyroid-stimulating hormone, reprogrowth hormone, prolactin, corticotrophin and melanocyte-stimulating hormone.

The Prehistory and Palaeogeography of the Great Indian Desert

Bridget Allchin, Andrew Goudie and Karunakara Hegde

March 1978, xx + 370pp., £25.00/\$48.90 0.12.050450.2

This is a study of the relationship between Stone Age cultures and changing environments in the Indian sub-continent during the latter part of the Pleistocene and Early Holocene. The authors have sought evidence of past climates differing substantially from that of the present time, and evidence of the presence of man noting in particular where the two were associated. Their field work in the desert and dry zone on its southeastern margins and in the Indus Valley showed that fluctuations in the extent of the Thar or Great Indian Desert and in the intensity of arid conditions in the region had provided a framework for environmental change.

The Systematics Association Special Volume No. 10

Modern Approaches to the Taxonomy of Red and Brown Algae

Proceedings of an International Symposium held at the Polytechnic of North London

edited by D. E. G. Irvine and J. H. Price

September/October 1978, xii + 486pp., £26.20/\$54.25 0.12.374050.9

The red and brown algae—mainly multi-cellular marine benthic organisms—offer challenging problems to the taxonomist. They are often difficult to study in the laboratory; comparatively simple in structure; often highly 'plastic' in form. The papers in this book present the proceedings of an International Symposium which was organised to bring together workers on widely different aspects of the red and brown algae; to evaluate the taxonomic potential of new data emerging from their researches; and to encourage interdisciplinary approaches. The papers provide a valuable contribution to algal taxonomy in themselves, while also indicating promising lines for future taxonomic research.

New and Forthcoming Books

THE TA-YOU WU FESTSCHRIFT: The Science of Matter

Edited in honour of Professor Ta-You Wu by Shigeji Fujita

A number of distinguished scientists, including three Nobel Prize winners, join here to dedicate their papers, to Professor Ta-You Wu, one of the founding fathers of modern physics, on his seventieth birthday. The papers include some original works, published here for the first time.

348pp 1978 0 677 13650 1 £30.60

HANDBOOK OF ASTRONOMY, ASTROPHYSICS AND GEOPHYSICS

Volume 1 The Earth 1: The Upper Atmosphere, Ionosphere and Magnetosphere

Edited by Charlotte W. Gordon, V. Canuto and W. Ian Axford

This important reference handbook is designed to bring together the foundations of knowledge in the field.

420pp 1978 0 677 04240 X £35.00

PLASMA ASTROPHYSICS: Nonthermal Processes in Diffuse Magnetized Plasmas

Edited by D. B. Melrose

Volume 1: THE EMISSION, ABSORPTION AND TRANSFER OF WAVES IN PLASMAS

This volume has been written primarily for graduate students in plasma astrophysics and for astrophysicists and geophysicists who wish to learn relevant plasma physics. Plasma theory is developed in a systematic way from first principles, and should be useful as a text for introductory plasma courses.

Approx 240pp 1978 0 677 02340 5 Approx £16.70

Volume 2: ASTROPHYSICAL APPLICATIONS

This companion volume to Volume 1 is intended as a reference, and includes astrophysical applications and source of the more advanced plasma theory. The presentation of the basic theory and especially of the astrophysical applications has been chosen to minimize the problem of outdating in such a rapidly developing field.

Approx 342pp 1979 0 677 02130 5 Approx £22.70

A PERSPECTIVE OF PHYSICS Volume 2

Introduced and edited by Sir Rudolf Peierls

Following the highly-acclaimed first volume of this annual serial publication, Sir Rudolf Peierls, F.R.S., considers in this volume the advances in modern physics for the year 1977.

296pp 1978 0 677 12400 7 £16.70

Programs of the Brain

J. Z. Young

Our lives are governed by sets of programs written in our genes and brains. Practical programs for breathing, eating, drinking, and sleeping; social ones regulating our speaking, agreeing, loving, or hating; programs concerned with sexual activity and mating, with growth and adolescence, with senescence and dying; and programs used for mental activities such as thinking, imagining, dreaming, believing, and worshipping. J. Z. Young's fascinating new book explores the whole range of human capacities and activities and how the brain works in influencing them. £5.95 28 September

Man and the Stars

Hanbury Brown

Why do we look at the stars? They have been a source of wonder and delight to man since primitive times, but does the study of stars have any use? The author sets out to show that it does, that astronomy has always been relevant to practical matters, and that the results are important, and familiar to us all. Illustrated £5.95

Flowering Plants of the World

Edited by V. H. Heywood

The flowering plants, or angiosperms, are the dominant group of plants on earth today, occupying a place in the plant world comparable to that held by mammals in the animal kingdom. There are at least 250,000 species of flowering plants grouped into between 250 and 350 families, and this book describes and illustrates in full colour the great majority of these families. The specially commissioned colour plates are beautiful as well as scientifically accurate, and the text is by a panel of internationally recognized authorities. Illustrated £7.95

Reconciling Man with the Environment

Lord Ashby

How should governments make the political decisions that are necessary to protect the environment? Lord Ashby traces the political process between the disclosure of a hazard to the environment and the action to remedy it, and the slow evolution of the public conscience from indifference to concern. £4.25

were in compiling the references. The text itself is rather brief in relation to the apparatus of references and indexes; 248 pages of text, tables and figures could hardly be expected to describe the references cited, let alone discuss them to any degree of thoroughness. Many important studies are given only a few sentences, whereas others are mentioned in a phrase or are lumped with other related papers in an overall characterisation. There is not much critical discussion of experiments or conclusions offered by investigators, although the authors occasionally point out discrepancies among reports and suggest some factors that complicate research and interpretation.

The title and prologue of the book may set up too high expectations by indicating that "... a theory for the 'Behavioral Code' is provided ...". Probably the emphasis should be placed on the word "elements", and perhaps "ingredients" would have been a more appropriate term. Table 80 lists as "Elements of the Behavioral Code" items as diverse as environmental stimulation, initiation of nerve impulses and transmitter release, effects on rates of synthesis of cyclic nucleotides, changes in synaptic efficiency, and

changes in learning, memory, and adaptive behaviour. Elsewhere in the book we are told that both short-term and long-term memory are elements and that "... neurotransmitter suspects [that is, presumed neurotransmitters] are integral elements of the Behavioral Code."

Apparently, although no definition is given, the Code when completed will include all of the events and processes that must intervene between initial capture of sensory information and storage of memory. Even the retrieval of memories should be included, although this book reflects most of the work in the field by not even mentioning retrieval. DeFeudis and DeFeudis believe, as do many workers in this field, that storage of memory requires a complex series of processes rather than depending upon some one key process. Their book is a substantial contribution towards the eventual formulation of a comprehensive theory of the neural mechanisms of learning and memory.

Mark R. Rosenzweig

Mark R. Rosenzweig is Professor of Psychology at the University of California at Berkeley.

Vertebrate visual system physiology

Handbook of Sensory Physiology. Vol. VII/5: The Visual System in Vertebrates. Edited by F. Crescitelli. (Springer: Berlin, Heidelberg and New York, 1978.) DM 340; \$149.60

THIS volume contains contributions by Crescitelli, Dvorak, Eder, Granda, Hamasaki, Holmberg, Hughes, Locket, McFarland, Meyer, Muntz, Munz, Olson and Reyer. The subject matter is concerned with the morphology, optics, pigments, physiology and adaptive radiation of the eye in different vertebrate classes. The chapters are comfortably short; most are under one hundred pages in length.

This volume is both necessary and important as a supplement to the earlier volumes in the *Handbook*. It is a necessary text for those libraries which deal with visual science, whether in its medical, biological or behavioural aspects, and is important in providing a source-book which is reasonably comprehensive and broad in outlook. It is occasionally suggested that large texts are on the verge of extinction

because of the rate of publication of new papers, and because they can be compendious rather than critical. The latter comment applies only in part to this volume, where a few sections might have been sign-posted better, and where the literature might have been treated more sceptically. Most research workers in vision could find flaws and omissions where their speciality has been touched on, yet would surely benefit from and be stimulated by the breadth and scope of this book.

Although it is probably unfair to pick out single contributions for comment, for all the chapters are of high quality, I was particularly fascinated by the treatment given by Hughes to comparative optics. This chapter shows how much more there is to retinal organisation in mammals than the cat, and is essentially a modern critical essay in the spirit of Gordon Walls.

I applaud this book, and hope that despite its price, it will be widely appreciated by students and research workers interested in vision.

A. L. Holden

A. L. Holden is at the Institute of Ophthalmology, University of London, UK.

Spectroscopic techniques

The Spectrum in Chemistry. By J. E. Crooks. Pp. 313. (Academic: London, New York and San Francisco, 1978). Hardback £12.60; paperback £6.50.

THIS is a straightforward textbook on spectroscopic techniques which are used in modern chemistry. All regions of the electromagnetic spectrum are covered, and the book is stronger than most of its rivals in the areas of X-ray spectroscopy, of photoelectron spectroscopy and of dispersion and dichroism associated with optically active materials. Indeed, chapter 9, which introduces optical activity through helices rather than asymmetrically substituted carbon atoms, is especially clear and a sufficient reason to recommend the work to undergraduate science libraries. The whole is well balanced and should be sufficient in depth for most British undergraduate courses. Thus, selection rules are briefly covered where appropriate but transition moments are not introduced. It is stronger on the general ideas and on spectroscopy in its own right than it is on quantum theory or on applications to organic or inorganic chemistry.

The author uses SI units, which is an attraction, although one wishes he did not so often remind the reader by attaching the units to the symbol for the physical quantity. For example, following equation (1.3), into which numerical values can be inserted using any set of coherent units, he adds:—"k is Boltzmann's constant in J K⁻¹". J K⁻¹ may prove convenient units but they are not essential and k stands for Boltzmann's constant in any units. The book has some 20 questions with answers. It also has its share of blemishes and errors, but these are mostly misprints or details which are wrong and do not detract from the qualitative message; they would be more important to the practitioner than an average student.

It is interesting that, as far as the reviewer can discover, Dr Crooks' personal research interests have been in rapid reactions and in solute transfer with emulsions, so that he is not an established expert in spectroscopy. There is much argument as to whether experts or others are to be preferred as undergraduate textbook writers: this book shows the demerit of the inexpert with its occasional errors, but also shows the merit of clarity and balance to be sought from 'an outsider'.

D. H. Whiffen

D. H. Whiffen is Professor of Physical Chemistry at the University of Newcastle-upon-Tyne, UK.

Extranuclear genetics

Extranuclear Genetics. By G. Beale and J. Knowles. Pp. 142. (Edward Arnold: London, 1978.) Paperback £5.95.

FEW areas of genetics have grown so rapidly and spread so pervasively as has extranuclear genetics in the short time since it achieved some measure of respectability. Whether one dates this from the discovery of DNA in extranuclear organelles or from the publication of the first textbooks to bring the wealth of the cytogenetical evidence for extranuclear hereditary systems to a wider audience makes no difference to the time-scale. It will, however, probably colour one's reaction to the balance of material and the historical perspective which Beale and Knowles present in their account of the subject.

The bulk of the material on extranuclear genetics *sensu stricta* is contained in three chapters devoted to mitochondria, chloroplasts and miscellaneous, respectively. A further chapter on endosymbionts and viruses provides background information from extranuclear systems which may have evolutionary and certainly have phenomenological affinities with the hereditary systems located in mitochondria and plastids. A fifth chapter on plasmids resists the efforts of the authors to justify its presence. A brief introduction and conclusions complete the contents.

The authors deliberately chose to present a relatively brief resumé of recent work on *Chlamydomonas* because of the availability of up-to-date accounts. Their decision to give even briefer accounts of the extensive work on flowering plants, much of it published in German, is, however, more a reflection of the overall strategy of the presentation, with its main emphasis on the molecular and fine structure and a lesser supporting role for genetic analysis. This emphasis shows up in many ways but probably the clearest is that of the total of 36 figures, 26 of which are electron micrographs; only one is a genetic analysis and that concerns an endosymbiont. There is a corresponding shortage or delayed description of the basic details of the life cycles of key organisms without which the genetical analyses are difficult to follow. For example, it is not until more than half-way through the chapter on mitochondria and after the sections on respiratory mutants and drug resistance that the timing of meiosis in yeast and the haploidy of the ascospores are first mentioned.

But it is not this imbalance but an overcautiousness in interpretation at times bordering on scepticism that concerns me most. The high point is where, with only two possible explanations, we are told that there are almost insuperable objections to both! Personally I find this depressing, others may well applaud it as scholarly. Indeed, *Extranuclear Genetics* presents a view of the subject that many and

Nature Vol. 275 21 September 1978

perhaps all recent converts and those coming into contact with it for the first time will find palatable and a more than adequate introduction. But I doubt whether many will find it stimulating.

J. L. Jinks

J. L. Jinks is Head of Department of Genetics at the University of Birmingham, UK.

Energy concepts

The Concept of Energy. By E. J. Hoffman. Pp. 573. (Ann Arbor Science: Michigan, 1978.) £18.60.

LET it be admitted at once that this book does not exactly appeal to this reviewer. But it is clear that the author has specialised knowledge in the field. He has written on extractive distillation (1964) and on energy transformations (1970) and is known in the fuel industry. As a result, his treatment of the "mathematical origins of the concept of energy" seems to strive for a universality including philosophy and differential geometry, which the author cannot attain. The result is an uneven

book with undue elaboration of the Joule-Thomson effect (28 pages) and enthalpies of mixtures (60 pages), and nothing is said about the economic assessment of alternative energy systems, the role of energy in biological systems or the reduction in status suffered by the energy concept at the hands of relativity theory. The references are mainly pre-1962 and there are doubts, which do not represent the scientific consensus, concerning relativity (p446) and the constancy of the Stefan-Boltzmann constant (p432). Nevertheless, the considerable effort made by the author is not wasted as the book may prove to be rewarding reading for those with an interest in the specialised topics mentioned above.

P. T. Landsberg is Professor of Physics at the University of Southampton, UK.

Phase transitions in solids

Phase Transitions in Solids: An Approach to the Study of the Chemistry and Physics of Solids. By C. N. R. Rao and K. J. Rao. Pp. 330. (McGraw Hill: Maidenhead, UK, and New York, 1978.) £18.15.

ALTHOUGH the subjects treated by Rao and Rao are fascinating, I found myself somewhat disappointed by the book itself. This survey of phase transitions in solids is impressively broad, covering topics such as crystal chemistry, nucleation and spinoidal decomposition, soft modes, and the modern theory of phase transitions. Perhaps as a result, the treatment of many topics is frustratingly incomplete and sketchy. The three paragraph discussion of the Peierls transition in one-dimension systems on pp 294-5, for example, is of little value to the uninitiated. Plots of the conductivity and resistance of KCP and TTF-TCNQ are shown, without a clear explanation of what is supposed to be going on. The authors refer rather mysteriously to a "giant Kohn anomaly", with no explanation of the physics. Platitudes and vague generali-

ties apparently taken from review articles are substituted for a critical evaluation of this field.

When the book discusses subjects in more detail, it often does so uncritically. For example, "Tizsa's theory of lambda transitions" is described exhaustively, even though it is almost certainly wrong. As presented by Rao and Rao, it seems to be merely an *ad hoc* hypothesis leading to an infinite specific heat. Most lambda transitions, including the one in superfluid helium, have very singular but finite specific heats, a fact not known to Tizsa when he proposed his "theory".

Notwithstanding its faults, this book is a useful source of references and information in the fields it attempts to survey. The numerous figures and illustrations of experimental data are stimulating, although not always clearly explained. I would not recommend this book for a course on the chemistry and physics of solids, as the authors suggest in the introduction. Were it not so prohibitively expensive, *Phase Transitions in Solids* might be worth acquiring as a reference for specialists.

M MACMILLAN
PRESS

Second Edition

THE EARTH'S TECTONOSPHERE ITS PAST DEVELOPMENT AND PRESENT BEHAVIOUR

J. H. TATSCH

We are pleased to announce that the first (1972) edition of *The Earth's Tectonosphere* has been completely revised. The new edition updates the results of our continuing research to determine the most probable geometrical, mechanical, thermal, and chemical aspects of the origin, evolution, and present behaviour of the Earth's upper 1000 kilometers. Included are about 80 of John C. Holden's inimitable drawings.

More specifically, this book is a multiple-hypothesis analysis of the development of the Earth's internal structure during the past 4.6 billion years, of how this deep structure has controlled the Earth's internal behaviour since the Earth began, and of why the surficial geophenomena and features are manifestations of that internal behaviour.

Chapter headings: 1, The origin of the solar system; 2, The Earth-Moon system; 3, The Tectonospheric Earth Model; 4, The Earth as a planet; 5, The crust of the Earth; 6, The tectonosphere; 7, The orogenic-cratonic structure of the continents; 8, The Earth's deep seismicity; 9, Global patterns of geothermal activity; 10, Intrusive and extrusive activity; 11, Morphology of the Earth; 12, Mountain building; 13, The Earth's gravity field; 14, Geomagnetism and polarity reversals; 15, Continents and oceans; 16, Sea-floor spreading; 17, Continental drift and polar wandering; 18, Plate tectonics and related omniductive processes; 19, Asteroids, meteorites, and tektites; 20, The Integrated Earth and its future.

The Tectonospheric Earth Model concept, developed in the first edition and repeated in this edition, differs essentially from other global-tectonics concepts in two salient respects: (1) it embodies the geometrical, mechanical, thermal, and chemical aspects of a driving mechanism that has existed during the entire 4.6 billion years that the Earth is believed to have been in existence; and (2) it encompasses the Earth's spatio-temporal framework to a depth of 1000 km during these 4.6 billion years.

The second edition attempts to show, as did the first, how these two differences permit a more meaningful interpretation of the origin, evolution, and present characteristics of the Earth's behaviour than is possible through other global-tectonics concepts. This pertains not only to the Earth's lithospheric plates but to all plates, blocks, and other forms of material that have evolved within the upper 1000 km of the Earth during the past 4.6 billion years.

The Tectonospheric Earth Model has been used as the basis for 10 correlative follow-on books: *Mineral Deposits* (1973), *The Moon* (1974), *Petroleum Deposits* (1974), *Copper Deposits* (1975), *Gold Deposits* (1975), *Uranium Deposits* (1976), *Geothermal Deposits* (1976), *Earthquakes* (1977), *Coal Deposits* (in press), and *Iron Deposits* (in preparation).

Available directly from the publisher or through book dealers in all parts of the world. Hard cover, 6 x 9 inches, 468 pages. Table of contents, line drawings, maps, bibliography, index. \$30. LC: 74-78917. ISBN: 0-912890-03-7. 1977.

No Hair

One of the transcendent creations of modern science, far surpassing those grade-school models of the double helix, is the phrasing in English of the “no-hair” theorem. In its original mathematical form it describes how structure and information are lost in a black hole, how the fundamental distinctions between baryon and lepton go the way of the trivial (to a physicist) differences between cow and tapeworm, corn and cob. In its English translation, the theorem has all the surface clarity and underlying complexity and humor of a perfect haiku. To wit: “A black hole has no hair.”

Such humor derives much of its appeal from the startling contrast between the real world (the one that we walk around in) and the world of physicists, where concepts of time, causality, and baldness are all bizarrely twisted. When one realizes that physicists are not kidding, it is hard to avoid a kind of... particularly for those of... into a...

See what LKB Ultrogel[®] your separ

LKB Ultrogel[®] is a new kind of which now turns gel filtration into nique. High resolution because of t istics of Ultrogel: small, rigid, unifor size-distribution.

When different Ultrogel types are used for serum fractionation, they can do this for you:

Bed dimen.: 1.2 × 55.6 cm
Flow rate: 5.0 cm/h
UV-detection: Curve 1, 280 nm T × 1 Curve 2, 254 nm T × 1

Bed dimen.: 1.2 × 46.8 cm
Flow rate: 5.0 cm/h
UV-detection: Curve 1, 280 nm T × 5 Curve 2, 254 nm T × 5

Bed dimen.: 1.2 × 48.8 cm
Flow rate: 2.6 cm/h
UV-detection: Curve 1, 280 nm T × 5 Curve 2, 254 nm T × 5

Buffer: 0.05M phosphate, pH 7.0, containing 0.171M NaCl and 0.02% NaN₃
Sample: 0.3 ml human serum (70 mg protein/ml)
Uvicord III
monitoring: For AcA 44, 100—0% transmission (T);
for AcA 34 and AcA 22, 100—80% T with automatic switching to 100—0% T

HUMAN SERUM PROTEINS SEPARATED ON LKB ULTROGEL.

IgG and albumin are indicated for the Ultrogel types AcA 44, AcA 34 and AcA 22. It is seen that AcA 44 is the best gel for separating IgG and albumin; with AcA 34 and AcA 22 the separation is reduced.

The void peak (arrowed) in AcA 44, containing proteins much bigger than IgG, is resolved into two peaks on AcA 34, and further resolved into three peaks on AcA 22.

Thus, for separating high-molecular weight proteins, AcA 22 is recommended, whereas AcA 44 is more suitable for fractionation of proteins with molecular weights around 100,000.

Ultrogel type	Effective fractionation range*
AcA 22	100,000 — 1,200,000
AcA 34	20,000 — 350,000
AcA 44	10,000 — 130,000
AcA 54	5 000 — 70 000

*Globular proteins

Shackman Instruments. The Shackman 7000 oscilloscope camera weighs less than 24 ounces and is highly portable. It produces high quality fully developed 83×108 mm prints with virtually no picture distortion in just 30 s. The 7000 needs no focusing, and exposure can be accurately controlled to take account of the brightness of the display and type of phosphor used. A range of ten hoods is available for hand-held operation to suit almost any oscilloscope. The hood is chosen to suit the oscilloscope bezel and simply fits to the camera body, retained by a locking ring. The light-tight hood allows only light from the cathode ray tube to reach the film and automatically centres and positions the camera at the correct distance from the display. The hoods are vacuum-formed from high quality ABS plastic. When the camera is permanently mounted to the oscilloscope a spacer body is fitted to the camera and matched to one of over 60 custom-made oscilloscope adaptors. At both sides of the adaptor are hinge pins which hold the camera firmly in position during exposure. Either pin can be removed to swing the camera to the left or right to allow the operator to have an unobstructed view of the screen. The spacer body is moulded from high quality ABS moulding, while the adaptors are made of lightweight aluminium alloy. They are designed to replace, or in some cases to fit onto, the bezel fitted by the oscilloscope manufacturer.

Circle No. 52 on Reader Enquiry Card.

Panasonic. The Panasonic Model NV-9200 is a high performance video cassette recorder for high quality colour or black-and-white recording and playback. It has a signal-to-noise ratio of better than 45 dB for outstanding picture quality, even with second and third generation tapes; high resolution is 330 lines black and white, 250 lines

colour. Controls are non-locking push-buttons with logic memory. The NV-9200 can be used as a slave player with Panasonic's new editing recorder, the NV-9500. The Model NV-9200 features still-frame playback, an optional remote control unit, NV-A152 that controls record, play, fast forward, rewind, stop and pause; automatic or manual control of video level with video level meter, two audio level meters, one for each channel, audio limiter, audio monitor output, tracking control, skew control, and automatic rewind at end of tape; also a direct drive video head cylinder motor for high stability and less jitter. The 'Auto Search' mode will stop fast forward or rewind when tape counter reads zero.

Circle No. 53 on Reader Enquiry Card.

Panasonic's AK-750 portable colour camera

Polaroid. The Polaroid CU-5 hard copy camera provides an easy, economical way for making permanent records of both repetitive and transient information from CRT screens. The CU-5 delivers a high contrast 8.3×10.8 cm photographic copy in seconds with either of two Polaroid instant black and white Land films. Type 107 C 3000 speed film that produces a finished record in 30 s that does not require coating, and Type 665—a 75 speed film that delivers simultaneously a fine grain print and a fully developed negative in 30 s without need of a dark room (the negative requires a brief clearing bath immediately after development). The computer or scope is tied up only a fraction of a second while the exposure is made. The finished print provides a permanent record as an easy-to-read print. Even dim readouts appear clear on Polaroid 3,000-speed black and white Land film. Since the prints develop outside the camera, you

can copy new information on the display immediately. This camera is available with accessory hoods for framing 8×10 cm oscilloscope screens and larger display screens up to 16.5×21.6 cm. With the addition of a power pack the CU-5 becomes a general purpose close-up camera capable of taking both colour and black and white close-up pictures from $\frac{1}{4}:1$ to three times life size. The Polaroid MP-4 camera is a copy, photomicrographic and photomicrographic recording system. It is stand mounted with eye-level reflex viewing. The new MP-4 can be converted for use as an enlarger by mounting its condenser enlarger head on the camera. Other Polaroid Land cameras and conventional cameras can be attached to the column using the universal camera mount.

Circle No. 54 on Reader Enquiry Card.

Zeiss. The Zeiss inverted microscopes IM 35 with automatic integrated 35-mm camera system and ICM 405 for fully automatic photomicrography on 35-mm or 4×5 -inch formats offer great ease of operation. Both instruments have a swing-back illuminator carrier which instantly clears the entire stage area to speed up the exchange of vessels, and allow easy micromanipulation. With condensers for long working distances, vessels and chambers of up to 20 mm thickness can be accommodated. A major advantage is the simple conversion into a high-performance fluorescence microscope. Almost any 35-mm camera back with focal-plane shutter and manual or motorised film advance can be attached.

Circle No. 55 on Reader Enquiry Card.

Gallenkamp. A new portable projection screen and a projector stand are now part of the Gallenkamp range. The screen is matt white, with a lenticulated surface which gives exceptional image definition over a wide viewing angle. The projection area is $1,220 \times 1,220$ mm and the height of the screen on its tripod stand can be adjusted between 540 and 870 mm. The screen will fold away for easy transport and storage when it is not in use. The projector stand will also fold flat. Made of strong tubular steel, it has a large table top (360×440 mm) and three adjustable height positions up to a maximum height of 1,110 mm.

Circle No. 56 on Reader Enquiry Card.

SECOND ANNUAL BRISTOL-MYERS AWARD FOR DISTINGUISHED ACHIEVEMENT IN CANCER RESEARCH

AWARD: \$25,000

DEADLINE FOR RECEIPT OF NOMINATIONS

December 31, 1978

ANNOUNCEMENT OF AWARD RECIPIENT

May, 1979

The Bristol-Myers Company presents an annual award to a scientist making an outstanding contribution in cancer research. The candidates for the Award are to be nominated by medical schools, free-standing hospitals and cancer research centers. Only one nomination from each institution is permitted.

SELECTION COMMITTEE

John E. Ultmann, M.D., Selection Committee Chairman
Director, Cancer Research Center, University of Chicago

Harris Busch, M.D., Ph.D.
Professor and Chairman, Department of Pharmacology
Baylor College of Medicine

Albert H. Owens, Jr., M.D.
Director, Oncology Center, The Johns Hopkins University

Saul A. Rosenberg, M.D.
Professor of Medicine and Radiology, and Chief, Division of Oncology
Stanford University School of Medicine

Alan C. Sartorelli, Ph.D.
Professor and Chairman, Department of Pharmacology
Yale University School of Medicine

Rules and official nomination forms are available from:
Secretary, Award Committee, 345 Park Avenue, Room 43-30,
New York, New York 10022.

A Textbook of Human Anatomy

EDITED BY W. J. HAMILTON

The new edition of this well-known and widely used textbook has been completely revised in order to bring it up-to-date with recent advances in fields of medicine such as immunology.

The number of illustrations has been considerably increased and includes some excellent four colour plates.

The format of the book has been enlarged and the layout clarified.

Price £14.50 768 pages ISBN 0 333 18115 8

Human Embryology

HAMILTON, BOYD AND MOSSMAN

Fourth Edition revised by

W. J. Hamilton and H. W. Mossman

This classic text has been the standard authority since it was first published in 1945.

In its revised form the fourth edition contains several new sections including a chapter on the development, structure and functional activities of the placenta and a large number of new micrographs.

Such a book will be an essential reference work for medical students, research workers, clinicians and surgeons.

This finely produced and scholarly book will remain the definitive English text for many years' *British Medical Journal*

£16.00 ISBN 0 333 19153 6

The Human Placenta

BOYD AND HAMILTON

The production of this book is a publishing event of importance. Two of the most distinguished anatomists with a special interest in the human placenta have combined, as often they have before, to write and of course illustrate a classic . . . Of course the book is expensive. Such a lavish feast of riches, the product of a lifetime's work and thought allied with the best of the publisher's art, could scarcely be otherwise. No department of anatomy, of obstetrics and gynaecology, of reproductive physiology, or of endocrinology, can consider its library complete without possessing a copy of this elegant informative volume'

Philip Rhodes *British Medical Journal*

£25.00 ISBN 0 333 19186 2

Surface & Radiological Anatomy

For students and General Practitioners

Fifth Edition

HAMILTON, SIMON AND HAMILTON

Increasing emphasis is now being given to the study of anatomical structures which are accessible to examination in the living subject and this beautifully produced book answers a need for an authoritative text on the subject.

In this fifth edition several changes have been made, many of the original micrographs have been replaced.

The editorial trinity have established a wonderful text; the association of an anatomist, a radiologist and a surgeon seems to be ideal' *The British Journal of Surgery*

£9.50 ISBN 0 333 19154 4

To order a copy of any of these books, please send the correct amount plus 50p per volume carriage, to Technical Book Services, P.O. Box 79, Maidenhead, Berkshire SL6 2EG.

6.9.77

newly on the market

Ion beam thinning unit. Ion Tech. Ion Tech announce the introduction of the Super Microlap. This incorporates two Model B11W water-cooled saddle field ion sources, controlled by a current regulated power supply unit to produce ion beams ranging in intensity from a few microamps to 500 μ A per source. For sensitive specimens, the low ion current capability and efficient water cooling guarantees freedom from ion source heat transfer and ion beam damage. The specimen can be mounted on a water-cooled or liquid nitrogen cooled stage. The ion sources operate at 10^{-4} Torr, and the fine beam is collimated by the internal electrode structure of the ion source and is independent of the cathode aperture diameter. Even after prolonged operation the ion beams remain collimated and do not spread. This equipment has the advantages of accurate ion source alignment, variable angle of incidence from normal to grazing and clean beams.

Circle No. 44 on Reader Enquiry Card.

The Super Microlap

Spectrophotometer. Perkin-Elmer. The models 554 and 555 are double beam UV/vis spectrophotometers scanning over the wavelength range 190–900 nm. The instruments feature microprocessor control of the abscissa and ordinate with keyboard entry of the operating parameters. Both instruments include automatic baseline correction, concentration calibration, auto zero, 1st and 2nd derivative, repetitive scanning and wavelength programming as standard. Abscissa and ordinate values are digitally presented and the Flowchart recorder is built-in, ensuring synchronisation of the chart with the monochromator.

Circle No. 45 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Form.

Automatic bomb calorimeter. Gallenkamp. The Gallenkamp Autobomb is an automatic instrument providing a convenient means of accurately determining calorific values to internationally accepted standards. The adiabatic system used ensures that heat losses from the calorimeter during the test period are negligible, thus eliminating the need for cooling correction calculations. Another important feature is the telescopic lift to which the top cover assembly is attached. This makes dismantling between tests unnecessary and also minimises the danger of breaking the calorimeter thermometer which need not be handled during testing. Heating is instantaneous and the water velocity through the jacket and cover is maintained at a high level to keep the temperature uniform.

Circle No. 46 on Reader Enquiry Card.

Liquid chromatography detector. Tracer. The Model 965 photo-conductivity detector for liquid chromatography, a highly selective halogen detector, has been announced by Tracer. Operating on the electrolytic conductivity principle, the detector senses any halogen-containing compound which will photolyse in the presence of UV light. The principal application will be pesticide analysis, since the detector is relatively insensitive to aromatic and other UV absorbing materials lacking halogen.

Circle No. 47 on Reader Enquiry Card.

Disposable protein concentrator. Millipore. The new immersible molecular separator II from Millipore gives the researcher a simple, rapid and economic means for concentrating or desalting solutions of proteins, macromolecule or viral suspensions. The Immersible II consists of an 11 cm² area ultrafiltration membrane cast on a porous core. The Pellicon membrane, with an exclusion limit of 10,000 daltons is specially formulated for high flux and minimum nonspecific binding. The unit is placed in the solution to be concentrated and a vacuum source connected. Low molecular weight salts and solvents pass through the membrane, while macromolecules >10,000 daltons remain in the solution. The Immersible II is available as a starter kit of 25 units with accessory tubing and connectors or as a refill kit of 25 ultrafiltration units only.

Circle No. 48 on Reader Enquiry Card.

Thermal microscope stage. Bailey. The TS-2, a solid-state thermal microscope stage cools or heats a specimen to a selected temperature within a -20°C to $+60^{\circ}\text{C}$ range and maintains that temperature indefinitely. The stage is thermoelectrically operated and produces a continuous cooling or heating effect. The TS-2 has no moving parts and is vibration free. The controller consists of a variable DC power supply and a microprobe thermometer which can be used independently for temperature measurements around the laboratory.

Circle No. 49 on Reader Enquiry Card.

The Bailey TS-2

Respiratory test meter. International Gas Apparatus. A portable meter capable of accurately measuring a patient's respiratory exhalation has been introduced by International Gas Apparatus. Based on a tried and tested principle widely used in their range of laboratory and research dry test meters, this respiratory meter is simple to operate and capable of measuring down to 0.001 cu. ft. Optional pressure and temperature gauges are available if required and various dial calibrations can be supplied to provide readings of 1/10 cu. ft or 1 cu. ft per revolution with sub-divisions of 0.001 cu. ft or 0.01 cu. ft, both models having a capacity of 115 cu. ft per hour. This test meter is designed for field or hospital use, and is only recommended for exhalatory use, not inhalation.

Circle No. 50 on Reader Enquiry Card.

Chlorophyllometer. Lars Ljungberg. The chlorophyllometer from Ljungberg is a fully transistorised photometer for the determination of chlorophylls in 100% acetone. The chlorophyllometer is a rapid and easily operated instrument with direct reading digital display (mg chlorophylls l⁻¹).

BIOLOGICAL PACIFISM

**Complete List of Academic Works of Noted Japanese Vegetarian,
NOBEL PRIZE CANDIDATE
DR HISATOKI KOMAKI, Ph.D.
(Now available free of charge)**

Internationally known Authority on the Theory and Practice of Vegetarianism

Dr Hisatoki Komaki's academic works and activities in the field of Biological Pacifism have won him worldwide recognition, including official nomination as a candidate for the Nobel Prize, along with the respected Dr Louis Kervran of France. In 1976, Dr Komaki was cited for his role in the organisation of the Int'l Academic Congress on the Happier Coexistence of All Living Things held at Kyoto University in Japan, and at the Sorbonne, in Paris, in 1977. Prior to becoming the Founder and President of Japan's Seibutsu Noogyoo Kenkyuusho Foundation and SALT Foundation (Hisatoki Komaki Foundation for the Salvation of All Living Things), Dr Komaki, a Ph.D. from Kyoto University, was a professor at Japan's Mukogawa University.

Biological Pacifism

Dr Komaki's extensive academic research into Biological Pacifism concludes that:

1. Even in the animal kingdom, the killing of mammals (animals possessing consciousness) is exceptional.
2. A meat-diet is uneconomic from the point of view of nutrition and food production. For, animals are the consumers of all essential nutrients, and the green plants are the producers of all of them. For example, as the definition itself shows, the ESSENTIAL AMINO ACIDS—the essential components of ANIMAL PROTEIN—can never be produced by animals (Carbohydrate, too. Fat, too. Vitamins, too. Of course . . .).
3. The only role of cattle-breeding—in past days—was the biological concentration (not production!) of the nutrients of plant origin. Today, of course, we have more scientific methods for concentration of the nutrients of plant origin.
4. Famous biological scientists like Professor Dr Munro Fox, of England; Professor Dr Paul Chauchard, of France, regard the cerebral system of animals except mammals, as a kind of mechanic system like an electronic computer, possessing no consciousness. Nobody, however, can conclude that fishes, birds or insects possess no consciousness. So . . . we, mankind, must stop the slaughter of mammals right now . . . and we must stop killing all kinds of animals as soon as possible.

Biological Pacifism and the Future Religion of Mankind

In his collected works, Dr Komaki concludes that:

1. "The Future Religion of Mankind" must possess a clear vision of and a concrete method for bringing about "Peace of All Living Things."
2. The Universal Life is not only the Universal Law but also the Universal PERSONA possessing the Infinite Love, Wisdom and Power. And, therefore, the all spiritual creatures must be immortal and must evolve to be completely happy.
If not, the infinite Universe is the infinite wickedness.
3. We do not know the true mechanism. It is supposed, however, that a man is the wonderful Complex of the living brain and the Psi Body or "Psi Information System". The life span of the latter is supposed to be endless or very long, while that of the former is very short. (Prof. Dr. Hideo SEKI's English monograph on the Psi Information System Hypothesis is obtainable from him, 5-11-3, Kamiura, Setagaya, Tokyo, Japan).
4. Only those religions, possessing the firm philosophical proofs of such truths, and, furthermore, possessing the effective method of the complete manifestation, or liberation, of the True Self, will occupy the main position in (or evolve into) "The Future Religion of Mankind", providing a vision and a method of realising "Peace of All Living Things".
5. Can we find such religious or philosophical movements in the present world? Dr Masaharu TANIGUCHI's SEICHO-NO-

IYE Foundation may be one of the best academic centres.

Christianity and Buddhism also possess each vision and each method. In Christianity, via a Mediator warranted by the fulfilment of the Biblical prophecies. In Nichiren Shoshu Buddhism, via a very rhythmical and powerful chanting of "the phonetic and ideographical expression of Cosmic Life" in front of a Mandala of the Cosmic Law.

Turning Biological Pacifism into a Working Reality

As a result of the series of Full Page opinion advertisements on Biological Pacifism that appeared in the "New York Times" Book Review section (April 16) New Statesman (April 14), etc., etc., significant public interest has been awakened. More attention is needed, however, to achieve the goals of Biological Pacifism.

Should 500 influential citizens donate £50 or \$100 each (per one year) in support of the campaign calling for a series of the full page opinion advertisements in first class newspapers and magazines around the world, Dr Komaki's academic conclusive ideas on Biological Pacifism can be spread all over the world within a few years' time.

Please DON'T send your donation now.

Instead, if you have any constructive ideas suggesting how effectively the captioned body be organised, please send to our U.K. or U.S. Liaison Offices.

The photo-copies of Dr. Komaki's all academic works are obtainable from the central libraries of the 66 countries over the world. For the complete list of the academic works of Dr Komaki (free of charge) or for additional information write to Seibutsu Noogyoo Kenkyuusho Foundation, Sakamoto-Honmachi, Otsu, Shiga-ken, Japan or its U.K. Liaison Office, Prof. Dr G. Herriot-Hunter, The Sanctuary, Yealmpton, Plymouth, PL8 2NB South Devon, England, or its U.S. Liaison Office, c/o Mrs Ethel R. Gans, 3 Bayne St., Norwalk, Conn 06851 U.S.A.

APPOINTMENTS VACANT

**CENTRAL ELECTRICITY
RESEARCH LABORATORIES**

Kelvin Avenue, Leatherhead, Surrey, KT22 7SE

Graduate/Postgraduate opportunities for Physical/Environmental Chemists

Opportunities exist for graduate/postgraduate chemists to join an active research team investigating chemical pathways of pollutants in the atmosphere. The work involved includes both basic laboratory studies and field work and it is anticipated that the successful applicants will among other activities help plan and implement experiments mounted in specially equipped sampling aircraft.

Applicants should hold a good honours degree in physical chemistry and have relevant research experience in some of these fields. We would also be pleased to receive applications from freshly qualified people interested in making an entry into these areas.

The Laboratories are situated in a pleasant part of Surrey and offer attractive Conditions of Service, and facilities for the total of 800 Research and Support staff engaged in a broad spectrum of research into the materials, technologies and plant performance problems of the Central Electricity Generating Board.

According to age, experience and qualifications the appointments will be made within incremental salary ranges rising to £6035 or £7050 plus a payment under a Self-Financing Productivity Scheme ranging between £8 and £17 per month.

Applications, quoting reference number RL/89, on standard forms which may be obtained from and returned to Dr. R. D. B. Whitcutt, Head of Personnel Services, at the above address. Application forms may be obtained by telephoning Leatherhead 74488 t. 363. Closing date is **Friday 6 October 1978.**

7157(A)

THE UNIVERSITY OF MANCHESTER RESEARCH BIOCHEMIST

Applications are invited from post-doctoral candidates for this post, to work on the mechanism of action and interaction of steroids and other hormones on bone. Work will be under the supervision of Dr D. C. Anderson, Senior Lecturer in Medicine (Endocrinology) at Hope Hospital Clinical Sciences Building, and in close collaboration with Dr S. R. Ayad, Senior Lecturer in Biochemistry. The project is for three years and will extend studies being currently conducted in this field. Previous experience with cell isolation and culture and/or hormone receptor techniques desirable. Starting salary: £3,883 to £4,382 p.a., according to age and experience, and rising according to Research Range 1A.

Send application with curriculum vitae, quoting names of two referees to Dr D. C. Anderson, Department of Medicine, Hope Hospital, Salford M6 8HD from whom further details may be obtained, by October 2, 7165(A)

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY University of London Queen Charlotte's Maternity Hospital Goldhawk Road, London W6 0XG

Applications are invited for the post of
**SCIENTIFIC PROGRAMMER
Grade 1B**

at the Institute of Obstetrics and Gynaecology, Queen Charlotte's Maternity Hospital.

Salary scale £3,384 to £5,604 plus £450 London Weighting Allowance.

The primary function of this post is to support a new PDP11 programmable remote-job-entry terminal connected to the University CDC computer installation. The work will involve a wide variety of software development using assembler and high level languages, plus experience of real-time programming. The successful applicant will work in a small, lively research department with a lot of scope for inventive development.

A scientific background (to Honours degree level) would be an advantage. Registration of a suitable candidate for a higher degree would also be a possibility.

Further details may be obtained from the Secretary, Institute of Obstetrics and Gynaecology, Chelsea Hospital for Women, Dovehouse Street, London SW3 6LT.

Applications, together with curriculum vitae and the names and addresses of 2 referees should be sent to: Dr G. S. King, Chemical Pathology Department, Queen Charlotte's Maternity Hospital, Goldhawk Road, London W6 0XG, Monday, October 16, 1978. 7213(A)

ST BARTHOLOMEW'S HOSPITAL London EC1A 7BE RESEARCH ASSISTANT

To work closely with consultant surgeon in laboratory, animal and clinical research. Applicants should have a good knowledge of microbiology and at least two years' research experience. Post vacant now and tenable until August 31, 1979.

Salary between £3,705 and £5,210 p.a. depending on qualifications and experience.

Please telephone 01-600 9000 ex 3320 (quoting ref: RP/90/25) for an application form and details of research being carried out.

Closing date for application October 5, 1978. 7148(A)

UNIVERSITY OF LONDON CHAIR OF CHEMICAL PATHOLOGY

TENABLE AT CHARING CROSS
HOSPITAL MEDICAL SCHOOL

Applications are invited for the appointment to the Chair of Chemical Pathology in Charing Cross Hospital Medical School, St Dunstan's Road, London W6.

The Medical School has an interest in the development of immunology, but candidates with special interests in other fields of chemical pathology are welcome to apply. The Professor will be Head of the Department of Chemical Pathology.

Duties will involve the forwarding of the subject, the teaching of medical students, conducting research, and the administration of the Department.

It is intended that the person appointed will take up his or her duties as soon as convenient, and be offered an honorary consultant contract with the Ealing, Hammersmith and Hounslow Area Health Authority (Teaching).

Further details should be obtained from the Academic Registrar (N Senate House, Malet Street, London WC1E 7HU before submitting applications (10 copies). Closing date November 20, 1978. 7163(A)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF CHEMISTRY

Postdoctoral Research Fellow to work with Drs M. C. Flowers and J. S. Ogden on a project supported by the Science Research Council and concerned with the investigation of the chemistry of laser evaporated species. The work involves the use of quadrupole and time of flight mass spectrometers and experience in mass spectrometry would be an advantage. The appointment is for one year commencing not later than December 1978. The salary will be £3,883 p.a. Applications with full curriculum vitae and the names of two referees should be sent either to Dr M. C. Flowers or Dr J. S. Ogden, Department of Chemistry, The University, Southampton SO9 5NH, as soon as possible. Please quote ref MA1/2/Na. 7174(A)

ADDRESS

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE : 01 831-6901

20 on Reader Enquiry Card

National Research Council Canada
Conseil national de recherches Canada

1979 RESEARCH ASSOCIATESHIPS

for research in science and engineering in the following laboratories of the NATIONAL RESEARCH COUNCIL OF CANADA:

ATLANTIC REGIONAL LABORATORY
DIVISION OF BIOLOGICAL SCIENCES
DIVISION OF BUILDING RESEARCH
DIVISION OF CHEMISTRY
DIVISION OF ELECTRICAL ENGINEERING
HERZBERG INSTITUTE OF ASTROPHYSICS
DIVISION OF MECHANICAL ENGINEERING
NATIONAL AERONAUTICAL ESTABLISHMENT
DIVISION OF PHYSICS
PRAIRIE REGIONAL LABORATORY

Applicants should possess at least a Ph.D. in natural science or a Master degree in an engineering field or expect to obtain the degree before taking up the award.

Associateships are open to nationals of all countries although preference will be given to Canadians.

Research Associates will be offered appointments to the staff of the National Research Council on a term basis and will be offered salaries and benefits currently available to members of the continuing staff.

The initial appointment will be for a one year term and may be renewed, subject to the Associate's performance and subject to the requirements of the Division. Renewals are considered annually. The term as a Research Associate will vary by Division but will not exceed five years.

An allowance will be provided towards the cost of travel.

Applications may be obtained from the Research Associates Office, National Research Council of Canada, Ottawa, Canada, K1A 0R6.

Closing date: 15 January 1979

7155(A)

REGIONAL CYTOGENETICS LABORATORY EAST BIRMINGHAM HOSPITAL LOCUM SCIENTIFIC OFFICER (Basic Grade)

Applications are invited for the locum post of Scientific Officer, initially for 3 months, with the possibility of a permanent post after 6 months. Experience in cytogenetics is essential but not absolutely necessary. Salary range depending on experience and qualifications, £2,991 to £4,899 p.a.

Application forms and further details available from the Regional Cytogenetics Laboratory, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST. Tel 021-772 4311 ext. 4354. 7192(A)

UNIVERSITY OF ABERDEEN DEPARTMENT OF BIO-MEDICAL AND BIO-ENGINEERING RESEARCH ASSISTANT

Applications are invited for this post which is supported by the Cancer Research Campaign for the investigation of the properties of overlapping ultrasonic fields and the instrumentation for producing and measuring them. Candidates should have first degree in Physics and Ph.D. in Physics or Bio-Physics or Electronics. The post is tenable initially for two years.

Commencing salary up to £4,300 per annum on the Range 1A Scale for Research and Analogous Staff, plus U.S.S.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by October 13, 1978. 7146(A)

LOTHIAN HEALTH BOARD METABOLIC UNIT

Western General Hospital

Applications are invited from candidates with an Honours degree in chemistry, biochemistry, or a biological science for the appointment of

BIOCHEMIST

(Basic grade)

In the above unit which is concerned with the management of and research into endocrine and metabolic disorders. Suitable candidates may register for a higher degree and may take part in the M.C.B. training programme run by the Departments of Clinical Chemistry.

Whitley Council conditions of service apply.

Further particulars may be obtained, or a visit arranged by contacting Professor J. A. Strong, University Department of Medicine, Western General Hospital, Crewe Road, Edinburgh EH4 2XU. Telephone: 031 332 2525, ext. 365.

Applications, which should be typewritten, giving the names and addresses of two referees should be lodged with the Secretary, 11 Drumshough Gardens, Edinburgh EH3 7QQ, by October 5, 1978. 7208(A)

UNIVERSITY OF LANCASTER DEPARTMENT OF ENVIRONMENTAL SCIENCES RESEARCH ASSOCIATE

A physicist at Ph.D. level is required for a programme of studies of the high-altitude ionosphere supported by the Science Research Council.

Applicants should be capable of managing a small observational programme, including data handling, as well as carrying through scientific ideas based on observational data. A research programme is essential.

The appointment will commence as soon as possible and terminate on February 28, 1982. Initial salary £130 (under review).

Further particulars may be obtained by writing reference L79/D) from the Establishment Officer, University House, Lancaster LA1 4YW, to whom applications (five copies), naming three referees, should be sent not later than October 9, 1978. 7167(A)

CSIRO AUSTRALIA Research Scientist

Division of Animal Health Armidale, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Immunology/Microbiology

General: The Division is currently reorganising its research programmes at McMaster Laboratory, Sydney and the Pastoral Research Laboratory, Armidale. The group at present comprises four senior parasitologists and an immunologist and it has been decided to diversify the activities of the group by the appointment of a second immunologist/microbiologist to work on aspects of staphylococcal disease. It is expected that the new appointee will develop some association with colleagues at the McMaster Laboratory in Sydney.

Duties: To carry out research into various aspects of staphylococcal immunity with particular reference to staphylococcal mastitis. Attention will be directed to determining the relative importance of various staphylococcal antigens as immunogens and to improving vaccination procedures.

Qualifications: A Ph.D. degree in a relevant discipline, or equivalent qualifications, supported by satisfactory evidence of research ability and experience appropriate to the field of study.

Salary: Research Scientist or Senior Research Scientist: \$A14,829 to \$A21,643 p.a. An outstanding applicant may be considered for appointment at a higher level.

Tenure: Indefinite with superannuation.

Applications **IN DUPLICATE**, stating **FULL** personal and professional details, the names and addresses of at least two professional referees, and **QUOTING REFERENCE NUMBER 201/563** should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON, WC2R 3EH, by October 23, 1978.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1801 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A. 7146(A)

HARPER ADAMS AGRICULTURAL COLLEGE Newport, Salop

LECTURER GRADE 2 in CROP PROTECTION

Applications are invited for a new post as Lecturer in Crop Protection. The person appointed will have responsibility for laboratory and field instruction and experimentation.

Candidates should have a degree in Agriculture or Horticulture together with postgraduate training and experience in Crop Protection.

Salary in Burnham F.E. Scale £4,101 to £6,658, point of entry dependent on qualifications and experience.

Further details and application form from The Bursar, Harper Adams Agricultural College, Newport, Salop, TF10 8NB. 7207(A)

CHANGE OF ADDRESS

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE: 01 831-6901.

Librarian

An opportunity has arisen for a Chartered Librarian to take charge of our Company Library at Ware.

The Library contains mainly scientific books and journals. It provides a service to scientists qualified in Biology, Chemistry, Medicine and Pharmacy, and also to members of Glaxo Operations Limited, a production Company on the same site. We are shortly to move into a modern, custom-built library which will have microfilm and reprographic equipment.

Candidates must be Chartered Librarians and have several years' relevant special library experience.

The position carries a competitive salary which will reflect the age and experience of the successful candidate. Other benefits include Flexitime working, pension and profit sharing schemes, extensive sports and social facilities, and assistance with relocation expenses where applicable.

Please apply to:
Dr Ian Collins, Personnel Manager,
Glaxo-Allenburys Research (Ware) Ltd.,
Ware, Herts. SG12 0DJ.
Telephone Ware 3232.

Glaxo-Allenburys Research (Ware) Limited

7178(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of
**POSTDOCTORAL
RESEARCH ASSISTANT**

to study collagen gene expression in cultured human chondrocytes in the DEPARTMENT OF BIOCHEMISTRY. The appointment, which is funded by a grant from the M.R.C. to Dr R. Harwood, is tenable for 3 years and is to be made as soon as possible. Previous experience of connective tissue or nucleic acid biochemistry would be advantageous, though not essential.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing date October 12, 1978. Please quote reference 1598. 7171(A)

GERMAN CANCER RESEARCH CENTER HEIDELBERG. POSTDOCTORAL RESEARCH ASSISTANT

Dept.: Molecular Biology
of DNA-Tumor-Viruses
Dr Gerhard Sauer, Head

Applications are invited from biologists or biochemists for the above post. The work will involve studies on the integration of the viral genome in the host cell DNA. The salary will be within the range of DM 2,900 to DM 3,100 depending on age. The appointment will be for up to two years starting on October 1, 1978.

Applications, stating age, academic qualifications and the names of two referees should be sent to Department of Administration, Deutsches Krebsforschungszentrum, 6900 Heidelberg, Im Neuenheimer Feld 280, Germany. 7201(A)

ST MARY'S HOSPITAL MEDICAL SCHOOL (University of London) Paddington W2 1PG DEPARTMENT OF PHYSIOLOGY POSTGRADUATE RESEARCH ASSISTANT

Applications are invited for the above post from candidates with a good Honours Degree in an appropriate field. The post is funded for a period of two years only by The Wellcome Trust and is available from October, 1978. The work involves research on the Physiology of Foetal Development. Salary would commence at £3,214 p.a. plus £450 p.a. London allowance. Applications, including a full curriculum vitae with the names and addresses of two referees to the Secretary, St Mary's Hospital Medical School, Paddington, London W2 1PG, quoting ref. N/HB/J. 7176(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF APPLIED BIOCHEMISTRY AND NUTRITION FOOD SCIENCE LABORATORIES A.R.C. RESEARCH ASSISTANTSHIP

tenable from October, 1978.

Applications are invited for the above post to study the dynamics of starch gelatinisation using one or more novel physicochemical techniques.

Candidates may register for a Ph.D. degree but should preferably have a good honours degree in Chemistry, Physics or some related subject.

Salary £3,384 to £3,883.

Applications, naming two referees, should be sent as soon as possible to: J. M. V. Blanshard, Dept. of Applied Biochemistry and Nutrition, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. LE12 5RD, from whom further details may be obtained. 7175(A)

THE QUEEN'S COLLEGE GLASGOW LECTURER

with good honours degree in Nutrition or Dietetics or a related science and preferably eligible for State Registration in Dietetics to teach Applied Nutrition and Diet Therapy at Degree and Diploma level. This is a new appointment.

Salary range: £4,056 to £7,167 (bar) to £7,698 per annum. (Full credit will be given for all relevant experience when calculating placement on this scale.)

A senior appointment may be available for an exceptional candidate. Assistance with removal expenses.

Further details and forms of application may be obtained from The Principal, 1 Park Drive, Glasgow G3 6LP to whom completed forms should be returned not later than Monday, October 16, 1978. 7149(A)

THE UNIVERSITY OF MANCHESTER DEPARTMENT OF PSYCHIATRY RESEARCH FELLOW IN NEUROPHYSIOLOGY

Applications are invited for this post (tenable until December 1980) to study the electrophysiological consequences of adrenoceptor activation in mammalian nerve cells using intracellular recording techniques. The appointee will collaborate with a small research team working within the field of cellular neuropharmacology. Applicants should possess a Ph.D., and have had research experience with neurophysiological techniques. Preferred starting date: January 1.

Salary range p.a. £3,883 to £6,555. Applications, with curriculum vitae and the names of two referees should be sent before October 31, to Dr E. Szabadi, Department of Psychiatry, University of Manchester, Stopford Building, Oxford Road, Manchester M13 9PT. 7166(A)

MAX-PLANCK-INSTITUTE West Berlin

There is a vacancy for a
**PHYSICAL CHEMIST
or BIOCHEMIST**

to work on physical properties of proteins and nucleic acids. Applicants with previous experience in this field will be preferred.

The position is available from January 1979 and is initially for 5 years with the possibility of renewal. Salary will be in the range 44,000DM/year (=£11,000=US\$22,000).

Applications are invited before December 1978 giving information about qualifications and the address of 2-3 referees. They should be sent to: Max-Planck-Institut für Molekulare Genetik, Personalbüro, Innestraße 63-73 D-1000 Berlin 33, Germany. 7209(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY DIVISION OF VIROLOGY RESEARCH TECHNICIAN

required from October 1, or as soon as possible, thereafter to join an active group studying the regulation of influenza virus gene expression. Qualifications: good degree, HNC or equivalent in biochemistry or microbiology. Experience in tissue culture or virology advantageous.

Starting salary up to £2,959 p.a. annum.

Applications and enquiries to B. W. J. Mahy, Division of Virology, New Addenbrookes Hospital, H. Road, Cambridge CB2 2QQ. Telephone 0223-45171, extension 313. 7211(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF MICROBIOLOGY

Applications are invited for the post of a postdoctoral Research Fellow in the Department of Microbiology.

The research which is under the direction of Professor H. R. Perkins will be concerned with the structure and biosynthesis of the bacterial cell envelope in relation to antibiotic action.

The post is financed by the M.R.C. and the initial salary will be within the range £3,883 to £5,129 per annum.

Applications, together with the names of two referees, should be received not later than October 9. The Registrar, The University, P. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/929/N. 7159(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSOCIATE

Applications are invited for the post of RESEARCH ASSOCIATE for work on the role of the recA and leu genes of E. coli in DNA repair and genetic recombination. The project is supported by a grant from the M.R.C. and the position is tenable for three years at a salary on the scale £3,883 to £6,555 under review. The work will involve combination of genetic and biochemical techniques and previous experience in protein purification, molecular cloning and DNA sequencing would be particularly advantageous.

Applications, including a curriculum vitae and the names of two referees should be sent to Dr P. T. Emmers, Department of Biochemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. 7160(A)

**UNIVERSITY OF BATH
SCHOOL OF CHEMICAL
ENGINEERING
TECHNICIAN**

A vacancy has arisen on a two year contract to assist in the development and design of a protein recovery process. Candidates should be qualified in Chemistry or Chemical Engineering to at least O.N.C., or 'A' level standard with industrial, or similar experience. Starting salary in the range £2,680 to £2,835 per annum (under review) depending on qualifications and experience. Application forms are obtainable from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 78/184R/N. Closing date will be October 9, 1978. 7169(A)

**HARVARD SUMMER
SCHOOL
POSITIONS IN BIOLOGY**
Applications are invited for Summer school teaching positions in Biology. Introductory courses are emphasised with possibility of intermediate offerings. Possible courses include: general biology, zoology, botany, cell biology, physiology, and genetics. Compensation at Harvard median. Applications including C.V. should be sent to: Dr Marshall R. Pihl, Associate Director, Harvard Summer School, 20 Garden Street, Cambridge, Mass. 02138. DEADLINE: October 31, 1978. Harvard University is an Equal Opportunity/Affirmative Action Employer. 7170(A)

**UNIVERSITY OF LEICESTER
THE MEDICAL SCHOOL
DEPARTMENT OF ANATOMY**
A vacancy exists for a POSTDOCTORAL RESEARCH ASSOCIATE to work with Professor Felix Beck on embryonic nutrition and teratology. The project, financed by the R.C., will involve embryonic culture, autoradiography and electron microscopy. Candidates should have experience of A.R.G. in particular. Initial salary £3,660 a year (under review). Applications to Professor F. Beck, Department of Anatomy, University of Leicester LE1 7RH, as soon as possible. 7205(A)

**THE UNIVERSITY OF
SHEFFIELD
DEPARTMENT OF
BUILDING SCIENCE
Building Aerodynamics
Research**

Applications are invited from men and women for a Research Post in the field of Building Aerodynamics. This post has been created by a Building Research Establishment contract to investigate the dynamic wind loads on buildings using wind tunnel techniques and is currently tenable, for a three year period. Some postgraduate experience in the use of experimental methods and data analysis is desirable and an appropriate background would be expected in one of the engineering or applied physics disciplines. Salary, dependent on age and qualifications, for a Postdoctoral appointment: on Range 1A up to £4,130 p.a.; for a Postgraduate appointment on Range 1B up to £3,660 p.a. These salaries will have anomalies correction of approximately 6% added to them following October 1, 1978. Further particulars may be obtained from the Registrar and Secretary, University of Sheffield, Sheffield S10 2TN to whom applications should be sent by October 6, 1978. Quote ref: R 199/G. 7191(A)

**UNIVERSITY OF
LIVERPOOL
DEPARTMENT OF
METALLURGY AND
MATERIALS SCIENCE**
Applications are invited for two posts of Senior Research Assistant. (a) On a project concerned with the effects of gas-ion bombardment on the microstructure of materials. Experience of transmission electron microscopy at the postgraduate level will be required. (b) To undertake theoretical research on an S.R.C. sponsored project concerned with the structure of defects in crystalline polymers. The initial salaries will be within the range £3,883 to £4,882 per annum. Applications should be received as soon as possible, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote. Ref: RV/932, A or B/N. 7193(A)

**UNIVERSITY OF BRISTOL
TSETSE RESEARCH
LABORATORY, LANGFORD
INSECT PHYSIOLOGISTS**
Applications are invited for two research assistantships to work with Dr P. A. Langley on various aspects of the physiology of tsetse flies. Areas of research are exploitation of the sex recognition pheromone in development of new control measures and the role of the neuroendocrine system in control of reproduction in tsetse. The first post is tenable from January 1, 1979 and the second at a date to be arranged in 1979, for three years. Selected candidates will be graduates with a first or upper second class honours degree and will have the opportunity to register for a higher degree within the University of Bristol. Salary will be commensurate with age and experience on the appropriate scales for research and analogous staff, e.g. £3,384 per annum at age 24. Applications, with curriculum vitae and the names of two referees, should be sent, before October 31, 1978 to The Director, Tsetse Research Laboratory, Langford House, Langford, Bristol BS18 7DU. 7183(A)

Lead a small, elite taskforce in high-temperature materials chemistry research.

If you're (1) a recognized leader in your own area for research, (2) have a strong background in physical and solid state chemistry including modern thermo-dynamics, and (3) have successfully lead group research efforts... you may well be the candidate we're seeking.

We're the Chemistry Division of Argonne National Laboratory—one of the nation's largest multi-disciplinary centres for basic and energy-related research. As the successful candidate for our High-Temperature Materials Chemistry group you'll be assuming Staff/Group Leadership responsibilities within a year of your appointment. You will also have an opportunity to develop new basic research programs and carry out your own research work.

Immediate specific responsibilities include leading a group of six highly-qualified researchers, and co-ordinating experimental and theoretical studies of:

- (A) Lattice defect and electronic structures of non-stoichiometric phases.
- (B) Thermodynamic properties of inorganic solids, liquids and gases at temperatures from 500 to 2,500°C.
- (C) Transport properties (diffusion and conductivity) of non-stoichiometric phases and kinetics of solid-gas reactions.
- (D) Interpretive and computational thermodynamic studies on the derivation of equations of state and transport.

For prompt, confidential consideration of your qualifications please send detailed resume outlining academic and other credentials to: Dr. Arthur D. Tevebaugh, Associate Director, Chemistry Division or to Mr.

Ronald A. Johns, Manager Employment Placement, Argonne National Laboratory, 9700 S. Cass Avenue, Argonne, IL 60439.

An equal opportunity employer, m/f 7204(A)

**ARGONNE
NATIONAL
LABORATORY**

**GREATER GLASGOW HEALTH BOARD
EASTERN DISTRICT
RESEARCH BIOCHEMIST**
Glasgow Royal Infirmary, Glasgow G4 0SF
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the above post to develop tests of thyroid function suitable for a programme of neo-natal screening for congenital hypothyroidism in Scotland. This collaborative project involving the department of Pathology, Biochemistry and Medical Genetics, University of Glasgow and Department of Bacteriology, Stobhill General Hospital, Glasgow is supported by the Biomedical Research Committee of the Scottish Home and Health Department.

Applicants should have a good honours degree in Biochemistry or related subjects and preferably a higher research degree. The salary will be within the basic grade scientist scale commencing £3,486 to £4,275.

Candidates are invited to visit the laboratories by arrangement with Dr J. G. Ratcliffe, Telephone No. 041-552 3535, Extension 5275, from whom further particulars are available.

Applications in writing giving two names for reference should be submitted to Dr J. G. Ratcliffe, Department of Biochemistry, Glasgow Royal Infirmary, Glasgow G4 0SF within two weeks of appearance of this advertisement. 7147(A)

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE : 01 831-6901

PERKIN-ELMER LIMITED OF BEACONSFIELD

We are a Company known the world over and recognised as one of the leading manufacturers of advanced analytical instruments used in industrial, medical and academic fields. We are an expanding company employing over 720 people.

Fringe benefits include 20 days holiday a year, plus one week off (with pay) at Christmas, subsidised canteen, and generous sickness benefit. All employees work a 37½ hour week and all are entitled to payment for overtime when required.

PRODUCT SPECIALISTS

Start a New Career in Sales

Due to expansion three vacancies exist: one for IR/NMR Spectroscopy, one for Electron Microscopy and one for Liquid Chromatography.

Applicants, male or female, must have instrumentation experience in one of the above-mentioned areas, and be aged 23-35 years with a recognised qualification.

The successful candidates will provide a technical and practical sales support to our Field Sales Force by running instrument demonstrations at our Beaconsfield facilities and at customer's laboratories when necessary. They will also be called upon to run product seminars and staff exhibitions.

I would be pleased to assist you in matching your qualifications and experience to our most suitable vacancy—so, if our products interest you and you would like to join a team of lively and energetic people, why not write to me or telephone for an application form.

Post Office Lane, Beaconsfield, Bucks. Tel: Beaconsfield 6161

COMMONWEALTH AGRICULTURAL BUREAUX Vacancy for SCIENTIFIC INFORMATION OFFICER at the

Commonwealth
Institute of Helminthology
The White House
103 St. Peter's Street,
St. Albans, Herts.

Duties: To assist in the preparation of *Helminthological Abstracts*, Series 1 Plant Nematology, and the Institute other publication in nematology.

Qualifications: Good degree in biology and ability to write clear and concise English essential. Training in plant nematology and knowledge of one or more other European languages advantageous.

Salary: In scale £2,839 to £5,448 plus London Weighting of £275 per annum and a compensatory allowance (taxable but not superannuable) of 3.3% of basic salary to offset personal contribution to Superannuation Scheme. Starting salary according to age, experience and qualifications.

Application forms and details from:
The Director,
Commonwealth Institute
of Helminthology,
The White House,
103 St. Peter's Street,
St. Albans,
Herts, AL1 3EW.
Closing date, October 20, 1978.

CHELSEA COLLEGE University of London POSTDOCTORAL RESEARCH ASSISTANT

is required to join a group working on lipids of plant membranes. Particular experience in the biochemistry and biophysics of lipids and lipid-water systems would be an advantage. The post is supported by the Agricultural Research Council and the appointment will be for a project approved for a period of three years. Salary in the range £3,660 to £4,130 per annum plus £450 London Allowance. Application forms and further details from the Personnel Officer, Chelsea College, Annexe, Friese Green House, Chelsea Manor Street, London SW3 3TW. Closing date October 9, 1978.

7164(A)

Applications are invited for: FREE-LANCE EDITORIAL WORK

on scientific manuscripts and proof for the Geology Department. Essential requirements are English as mother tongue, an appreciation of good English style, a meticulous eye for detail, and some background in Earth Sciences. Applications, in writing, with details of experience and qualification (including specialist field of study should be addressed to Mr P. Hardorff Elsevier Scientific Publishing Company, P.O. Box 330, 1000 AA AMSTERDAM, The Netherlands.
7168(A)

RESEARCH TECHNICIAN for Department of Anatomy to assist group in study of the development of lymphocytes. Extensive tissue culture and the use of a variety of immunological techniques are involved. Previous experience and appropriate qualifications essential.

Instruction will be given in techniques related to Tissue Culture and Immunology. Salary in the range of £2,689 to £3,087.

Ref. 401/C/327. Application form from, Assistant Secretary, Personnel Office, University of Birmingham P.O. Box 363, Birmingham.

7188(A)

EEC PHARMACEUTICAL COMPANY

seeks

DIRECTOR OF RESEARCH

The successful candidate will report directly to the Managing Director and should have particular capabilities in:

- Creativity and initiative substantial experience in pharmaceutical research.
- Strong background in pharmacology.
- The company is medium sized, located in Paris and is already actively engaged in international development and licensing.
- It's research facilities employ approximately 100 people.
- Nationality indifferent, fluent English and French essential.

Please write to: SODECI, 140 Rue de la Croix Nivert, 75015 Paris (France).

7214(A)

HARPER ADAMS AGRICULTURAL COLLEGE Newport, Salop

SENIOR LECTURER in AGRICULTURAL CHEMISTRY

Applications are invited for the above post available from January 1, 1979. The person appointed will be responsible for the teaching and research work in the Agricultural Chemistry Unit.

Candidates should have a degree in Agricultural Chemistry with a particular interest in Animal Nutrition.

Salary in Burnham P.E. Scale £6,051 to £7,315, point of entry dependent on qualifications and experience.

Further details and application form from: **The Bursar, Harper Adams Agricultural College, Newport, Salop, TF10 8NB.**

7206(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London) Denmark Hill, London SE5 8RX RESEARCH BIOCHEMICAL TECHNICIAN

to work in Cardiac Research Laboratory in King's College Hospital (Dr D. Jewitt). Project involves assessment of new drugs designed to prevent abnormal heart rhythms after coronary thrombosis. The technician will be responsible for plasma drug level estimations. Experience of spectrofluorimetric and gas chromatographic techniques an advantage. H.N.C. qualification required. Salary according to age, qualifications and experience. Further details may be obtained from Dr D. Jewitt, telephone 01-274 6222 ext. 2500.

Applications to the Secretary of the Medical School at the above address. Please quote reference EJ/N.

7162(A)

UNIVERSITY OF BIRMINGHAM FACULTY OF SCIENCE AND ENGINEERING CHAIR AND HEADSHIP OF THE DEPARTMENT OF MATHEMATICAL STATISTICS

Applications are invited for the Chair and Headship of the Department of Mathematical Statistics which will become vacant from October 1, 1978 on the retirement of Professor H. E. Daniels.

Salary in the professorial range plus superannuation.

Further particulars available from the Registrar, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (12 copies: 1 from overseas applicants), naming three referees, should be sent by October 30, 1978.

7189(A)

UNIVERSITY COLLEGE LONDON DEPARTMENT OF PHYSICS AND ASTRONOMY TWO POSTDOCTORAL RESEARCH ASSISTANTS

Required as soon as possible for the development of systems and applications software for the Interactive Analytical Image Processing System (IAPS), being built jointly by the Appleton Laboratory and University College London. Candidates should possess a Ph.D.; also for applications software preferably a good knowledge of dynamical meteorology, image processing and FORTRAN programming and for systems software a good knowledge of systems programming. Starting salaries will be in the range £3,359 to £4,858 including London Allowance.

Applications with Curriculum Vitae and the names and addresses of two referees should be sent to Dr G. E. Hunt, Department of Physics and Astronomy, University College London, Gower St., London WC1E 6BT.
7197(A)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY RESEARCH FELLOW

Applications are invited for a position to work with Dr R. S. Jones and Professor D. V. W. Parke on an R.C. supported project concerned with an aspect of environmental carcinogenesis. Applicants (male or female) should be graduates of either chemistry or biochemistry and possess a Ph.D./D.Phil. Experience in P.L.C. and/or other analytical techniques would be beneficial but not essential.

The appointment is for a period of 3 years, commencing on January 8, 1979 at a starting salary of £3,660 per annum (Range 1A).

Applications, in the form of a curriculum vitae, including the names and addresses of two referees, should be sent to the Assistant Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH to be received by: October 5, 1978.

Further information may be obtained from Dr R. S. Jones, in the Department of Biochemistry.
7181(A)

UNIVERSITY OF ABERDEEN RESEARCH ASSISTANT IN PHYSIOLOGY

Applications are invited for the above post from Graduates in Physiology, Pharmacology or Biochemistry, to work with Dr D. M. Campbell and Dr M. A. Radcliffe on maternal fat metabolism in pregnancy. Appointment is tenable for three years to commence as soon as possible.

Commencing salary £3,384 rising to £3,883 per annum, on Range 1B Scale of Research and Analogous Staff.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by October 6, 1978.
7144(A)

UNIVERSITY COLLEGE CARDIFF DEPARTMENT OF PLANT SCIENCE POSTGRADUATE OR POSTDOCTORAL BIOCHEMIST

Applications are invited for a POSTGRADUATE or POSTDOCTORAL

RESEARCH ASSISTANTSHIP to work on nucleic acid metabolism in tomato seeds under the supervision of Dr J. A. Bryant. The post is available for 15 months in the first instance, with the possibility of renewal. Salary within Research and Analogous Staff Range 1B: £3,384 to £4,631. Duties to commence as soon as possible.

Applications (2 copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, from whom further particulars may be obtained. Closing date October 5, 1978. Please quote reference 1601.
7184(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

LECTURER IN ANALYTICAL CHEMISTRY IN THE DEPARTMENT OF CLINICAL PHARMACOLOGY

Applications are invited for the above post, from persons possessing a Ph.D. degree in Chemistry or Biochemistry, and postdoctoral research experience in the use of sophisticated analytical techniques, especially GC-MS, in medical research. Some knowledge of synthetic organic chemistry would be an advantage. The successful candidate will be responsible for the direction of the Department's analytical laboratory which is equipped with a full range of instruments including Finnigan 3200 and Finnigan 4000 GC-MS-computer systems, and will also be encouraged to develop an independent line of research. Salary in the range for non-clinical lecturers (from October 1, 1978): £3,883 to £7,754 a year plus £450 London Allowance. Superannuation under U.S.S.

Applicants should apply by letter enclosing six copies of their curriculum vitae, to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS, quoting ref. no. 20/3/N. Closing date October 7, 1978.
7152(A)

EAST MALLING RESEARCH STATION PLANT PATHOLOGY DEPARTMENT A VIROLOGIST

to join team working on virus and virus-like diseases of fruit and hop plants.

Applications invited from graduates with honours degree or ordinary degree or HNC in virology, microbiology, or plant pathology.

Appointment Scientific Officer grade (£2,839 to £4,415) or Higher Scientific Officer grade (£4,101 to £5,448) depending on qualifications and experience.

Details and application form from Secretary, East Malling Research Station, East Malling, Maidstone, Kent ME19 6BJ.
7176(A)

Scientific Officer/ Higher Scientific Officer £2,839 to £5,448

Applications are invited for a pensionable post in the Field Botany Division of the Department of Agriculture situated at Newforge Lane, Belfast.

The successful candidate will carry out research in the field and under controlled environmental conditions aimed at increasing productivity and utilisation of pasture in hill land in Northern Ireland. The successful candidate may also be required to undertake lecturing duties in the Faculty of Agriculture and Food Science, Queen's University, Belfast.

HIGHER SCIENTIFIC OFFICER

Under 30 years of age at 31 December 1978 and possess a 1st or 2nd Class Honours Degree in Agricultural Botany, Agriculture or Botany and at least 2 years' appropriate postgraduate experience.

SCIENTIFIC OFFICER

Under 27 years of age at 31 December 1978 with an Honours Degree as above.

Preference may be given to candidates with knowledge of soil science.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

SALARY SCALES

Higher Scientific Officer—£4,101 to £5,448

Scientific Officer—£2,839 to £4,415

Please write or telephone for an application form quoting job reference SB 314/78/N to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR. (Telephone Dundonald 4585 ext. 256). Completed forms must be returned to arrive not later than October 5, 1978.
7142(A)

Scottish Institute of Agricultural Engineering SOILS SECTION

SENIOR SCIENTIFIC OFFICER/PRINCIPAL SCIENTIFIC OFFICER (Ref. AG/18/A) (Re-Advertisement)

Applications are invited for the post of Senior Scientific Officer/Principal Scientific Officer to lead a team investigating the effects of agricultural machinery on the physical properties of field soils with particular reference to cultivations, zero-tillage and compaction.

QUALIFICATIONS: A first or upper second-class Honours Degree, and preferably a higher Degree, or equivalent qualifications in a relevant branch of Science or Engineering. The applicant should have had considerable experience of research in soil physics or soil mechanics.

SALARY SCALES: Appointment in the grade of Senior Scientific Officer (£5,154 to £6,898) or Principal Scientific Officer (£6,609 to £8,461) according to qualifications and experience. Non-contributory superannuation.

Application forms and further information from:—

The Secretary, Scottish Institute of Agricultural Engineering, Bush Estate, Penicuik, Midlothian EH26 0PH.
to whom applications should be submitted by October 6, 1978. 7120(A)

CHANGE OF ADDRESS

The Advertisement offices for NATURE have moved to
3 DYERS BUILDINGS, LONDON, EC1N 2NR
TELEPHONE : 01 831-6901

EUROPEAN MOLECULAR BIOLOGY LABORATORY EMBL

The European Molecular Biology Laboratory is an international research institute founded by 10 member states (Austria, Denmark, France, Federal Republic of Germany, Israel, Italy, Netherlands, Sweden, Switzerland, United Kingdom) with its Central Laboratory in Heidelberg, Germany and two out-stations in Hamburg, Germany and Grenoble, France.

Applications are invited for the post of

DIRECTOR OF ADMINISTRATION

Applicants should be nationals of the member states, in the age range 45-55 and should have substantial responsible experience in management and preferably of scientific administration. Experience of international organisations would be an advantage. Fluency in at least two of the three official languages (French, English, German) as well as a reasonable working knowledge of the third, is essential.

The successful applicant will be located in the Central Laboratory at Heidelberg and will be offered the basic salary, net of tax, of DM 6300 monthly or higher according to qualifications. Additional allowances are payable according to personal circumstances.

Applications should be addressed to:

Sir John Kendrew, EMBL, Postfach 10.2209, D-6900 Heidelberg, Germany. 7140(A)

TECHNICIAN (HISTOPATHOLOGY)

Qualified to at least ONC level, with the relevant background, to assist in the work of the Histopathology Laboratory of the Division of Viral Products. This involves the preparation and examination of tissues from experimental animals inoculated with human virus vaccines. Although training will be provided, experience in the preparation and processing of tissues and competence in handling laboratory animals would be an advantage.

The post offers prospects for promotion. Salary up to £5,034 depending upon experience and qualifications.

The Institute is situated in pleasant surroundings, close to Hampstead Underground Station, but is expected to move to new premises outside London in 4-5 years' time. Please write, or telephone, for an application form, quoting reference number 0140, to The Personnel Officer, National Institute for Biological Standards & Control, Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232 extn. 211.

7199(A)

NIBSC

National Institute for Biological Standards and Control

UNIVERSITY OF OXFORD DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT GRADE 1A

(3 Year Appointment)

Applications are invited for a Post-doctoral Research Assistant supported by the S.R.C. and tenable for three years, to work with Dr Peter C. Newell on genetic aspects of development in the cellular slime mould *Dictyostelium*. The project will employ the parasexual cycle of this eukaryotic micro-organism to study the genetic loci involved in the production of a simple morphogen that controls the course of differentiation. The appointment will commence on November 1, 1978, or soon after, on the salary scale £3,660 to £4,601 (under review). Applications, including the names of two referees, should be sent to The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU by October 28, 1978. 7195(A)

OXFORD UNIVERSITY PHYSICAL CHEMISTRY LABORATORY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a two-year post to study the binding of a hormone or drug to a receptor site by the method of computer simulation. The project is supported by the Medical Research Council, and the post will be on the 1A Scale at a starting salary of up to £4,130 and with membership of U.S.S. Applicants experienced in computer programming should write for further particulars to Professor J. S. Rowlinson, Physical Chemistry Laboratory, South Parks Road, Oxford OX1 3QZ. 7180(A)

UNIVERSITY OF BRISTOL DEPARTMENT OF PATHOLOGY RESEARCH ASSISTANT (£4,382 to £5,367)

Applications are invited for the above post from biological scientists with experience in cell membrane protein biochemistry, and immunology. The successful applicant will join a new M.R.C. funded 5-year programme to investigate the use of membrane antigens as a possible EB-virus vaccine as part of a wider study; technical help will be available. The appointment will be for one year initially renewable annually. Replies in writing giving the names and addresses of two referees to Professor M. A. Epstein, Department of Pathology, The Medical School, University Walk, Bristol BS1 1TD, by October 6, 1978. 7185(A)

MCGILL UNIVERSITY BIOCHEMISTRY DEPARTMENT STAFF POSITION ASSISTANT PROFESSOR

to teach graduate and undergraduate courses, supervise students and maintain an active independent research program. Preference will be given to the general area of enzyme regulation in mammalian cells. Candidates should have at least two years of postdoctoral experience. Curriculum vitae, including the names of at least three persons who can be contacted for letters of reference, should be sent to:

Dr W. Mushynski,
Search Committee,
Department of Biochemistry,
McIntyre Medical Sciences Building,
McGill University,
3655 Drummond Street,
Montreal, Quebec,
Canada H3G 1Y6. 7203(A)

PLANT BREEDING INSTITUTE Maris Lane, Trumpington Cambridge CB2 2LQ CYTOGENETICS DEPARTMENT SCIENTIFIC OFFICER

A Scientific Officer is required to undertake under the supervision of Dr. M. D. Bennett experimental studies of reproductive cell development in cereals with special emphasis on premeiotic and meiotic chromosome behaviour, and of variation in the amount and type of chromosomal DNA within and between higher plant species, particularly crop plants and their relatives, using a wide range of cytochemical, autoradiographic, light and electron microscopy techniques.

Candidates should have an honours degree or equivalent in biology, chemistry and/or physics; or a postgraduate degree, HNC or equivalent with relevant post-qualifying experience. Laboratory experience in electron microscopy or cytology would be an advantage.

Starting salary will be according to qualifications and experience on scale rising from £2,839 p.a. to £4,415 p.a. Non-Contributory Pension Scheme.

Applications with curriculum vitae and names addresses of three referees should be submitted to the Assistant Secretary (Establishment) not later than 9th October 1978. 7194(A)

TEMPORARY MEDICAL LABORATORY SCIENTIFIC OFFICER IN HISTOPATHOLOGY

Qualified technician required for months only. Hospital experience in Histopathology essential.

Application form from the Personnel Department, Royal Marsden Hospital, Fulham Road, London SW3. Tel: 01-352 8171 Ext. 447. 7187(A)

**UNIVERSITY
OF MANCHESTER
DEPARTMENT OF MEDICAL
BIOCHEMISTRY
POSTDOCTORAL
RESEARCH ASSISTANT
IN BIOCHEMISTRY**

A postdoctoral research assistant sponsored by the Medical Research Council is required from October 1978 earlier if preferred. The work, under the supervision of Jacqueline B. Weiss, involves the characterisation of spatial recognition of new collagen alpha chains and the person appointed will be part of a multi disciplinary team of whom one is an electron microscopist. Experience in collagen biology or biochemistry would be very welcome but experience in general protein chemistry would also be acceptable. The appointment is for three years only. The salary scale is in the range £4,365 to £4,834 p.a. Applications, including curriculum vitae, to Jacqueline B. Weiss, Senior Lecturer, Department of Medical Biochemistry, Medical School, Stopford Building, Oxford Road, Manchester M13 9PT. 7075(A)

CHAIR OF GEOLOGY

Applications are invited for a further Chair of Geology which is to be established during the academic year 1978/79.

Salary within the professional range. Applicants may have teaching and research interests in any field of study appropriate to a University Department of Geology.

Further particulars may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH. Send applications (10 copies from applicants in the United Kingdom) to be submitted before November 5, 1978. 7130(A)

**THE UNIVERSITY OF THE
WEST INDIES, TRINIDAD**

Applications are invited for the post:

**LECTURER/ASSISTANT
LECTURER IN INORGANIC
CHEMISTRY**

Post is to be filled for Academic year 1979/80. Salary Scales: Lecturer: £19,071 to 29,799 p.a. Assistant Lecturer: TT\$15,480 to 16,974 p.a. (sterling=TT\$4.62). F.S.S.U. Unfurnished accommodation if available 10% or furnished at 124% or housing allowance of 20% of pensionable salary. Up to five full economy passages on appointment and on normal termination. Study and Travel Grant. Detailed application (2 copies) with curriculum vitae and naming three referees to be sent direct as soon as possible to Secretary, University of the West Indies, St Augustine, Trinidad.

Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, LONDON W1P 0DT. Further details may be obtained from her address. 7179(A)

research**

Biological Evaluation Scientist

Our Environmental Safety Division has a vacancy for a Biological Evaluation Scientist.

The Division carries out basic research in toxicology and is responsible for the toxicological safety of Unilever Products.

The Scientist appointed will be responsible for the planning and implementation of tests to assess the safety of substances on skin.

Candidates, of either sex, should have a good Honours degree in a bio, biochemical science and three or more years post graduate experience leading to a Ph.D or at an equivalent level. Training or experience in toxicology particularly the skin area would be an advantage, but is not essential.

The Colworth Laboratory is located on a very attractive 1200 acre country estate ten miles north of Bedford. A competitive salary will be offered and an excellent benefit package includes BUPA and assistance with re-location expenses, where appropriate.

Please write quoting Ref. CH-228M and giving details of career history to:

**Miss J. Kenny,
Personnel Officer,
Unilever Research,
Colworth Laboratory,
Colworth House, Sharnbrook,
Bedford MK44 1LQ.**

7172(A)

**UNIVERSITY OF DUNDEE
DEPARTMENT OF
BIOLOGICAL SCIENCES
Applications are invited for a
RESEARCH ASSISTANT**

to work in the above Department under the supervision of Dr M. J. Daft.

The post is financed from an external grant and will be available for up to three years. The investigation is on interactions and competitive effects amongst different endomycorrhizal crop plants. Applicants should have an Honours Degree in Biology.

Salary scale £3,189 to £3,660.

Applications, in writing, containing the names of two referees should be sent to The Secretary, The University, Dundee DD1 4HN. Please quote Ref: EST/58/78J. 7158(A)

**UNIVERSITY OF
NOTTINGHAM
RESEARCH ASSISTANT IN
BIOLOGICAL CHEMISTRY**

To work on the isolation and identification of novel antibiotics from hybrid fungi and actinomycetes. The position which is tenable for two years in the first instance requires a graduate with a good degree in either Chemistry or Biochemistry, preferably with a knowledge of microbiology.

Salary £3,384 per annum (Under review).

Further particulars and forms of application, returnable not later than September 30, 1978, from the Staff Appointments Office, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. 630. 7153(A)

DELALANDE Research Center

wishes to recruit an additional research worker in the area of

pharmacokinetics and drug metabolism

Applicants should already be working in this field and should have a PhD or equivalent qualification. Knowledge of French is not essential.

DELALANDE is an international pharmaceutical company actively engaged in research. The Research Centre is situated in attractive surroundings close to Paris and is within easy reach of main road and rail routes.

Applications should be sent to:

M. STROLIN BENEDETTI

Head, Biochemical Pharmacology

Centre de Recherche DELALANDE

Department of Agriculture and Fisheries for Scotland

Agriculturist a specialised role in potato agronomy

The Agricultural Scientific Service undertakes a wide variety of experimental projects including seed testing, National List testing of new varieties of crops, seed and planting stock certification schemes and the development of plant health standards.

This post offers an experienced agriculturist the opportunity to develop and manage the production and distribution in Scotland of virus-tested nuclear and commercial seed potato stocks under quarantine conditions. The successful candidate will also help to monitor nuclear clones for potato leaf roll virus, will control work on the Department's potato variety and disease collections, plan and organise experimental projects, mainly in physiology and agronomy, and assist in training potato inspectors and specialist agricultural staff. Candidates, normally aged under 32, should preferably have a good honours degree in agriculture, botany or close related subject, and must have a sound knowledge of potato agronomy and physiology and a good appreciation of potato diseases and their control.

Appointment as Senior Scientific Officer (£5150-£6900) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 12th October 1978) write to Scottish Office, Personnel Division, PM(PTS)3, Room 404, 16 Waterloo Place, Edinburgh EH1 3DN, telephone Edinburgh (031) 557 2090 ext 283/248. Please quote ref: SA/17/DLA.

CIVIL SERVICE

UNIVERSITY OF LONDON INSTITUTE OF NEUROLOGY

Muscular Dystrophy Research Laboratories, Institute of Neurology, London. Postdoctoral position is available for a biochemist to study cell surface glycoproteins and glycolipids of muscle from a recessive genetic disorder grown in culture. Experience with techniques of surface labelling and isolation of membrane lectins would be of value. Position is available October 1. Starting salary is £4,155 (at age 26) plus London Allowance. Send curriculum vitae and names of three referees to Dr E. J. Thompson, Neurochemistry, Institute of Neurology, London WC1N 3BG.

7150(A)

TECHNICIAN GRADE 2B

required for the Zoology Department to work in the photographic unit and occasionally in other areas of the Department. City and Guilds 744/745, O.N.C., or equivalent qualifications and three years experience required preferably in the above discipline. Day release scheme for further training. Salary on scale £2,994 p.a. rising to £3,345 p.a. (inclusive) 4 weeks annual holiday. Contributory pension scheme. Apply in writing with full details to: The Head Clerk, Ref. 204011/N, King's College London, Strand WC2R 2LS.

7186(A)

A.R.C. ANIMAL BREEDING RESEARCH ORGANISATION ASSISTANT BIOMETRICIAN

Required for research on the genetics of growth in relation to animal production. The work involves analysis of a wide range of data and participation in the conduct of experiments. Applicants should have an honours degree in a relevant subject and some ability in computing. Appointment as Scientific Officer (£2,839 to £4,415) with starting salary depending on qualifications and experience. Non-contributory superannuation. Further information and application forms obtainable from the Secretary, A.R.C. Animal Breeding Research Organisation, West Mains Road, Edinburgh EH9 3JQ. Closing date October 7, 1978.

7141(A)

PRE AND POSTDOCTORAL POSITIONS

are available for studies on the protein synthesising system with special emphasis on ribosomes—topography, biogenesis and function—under various conditions of growth and development. Teaching opportunities available. Reply with résumé to:

Professor Bruce H. Sells,
Laboratories of Molecular Biology,
Faculty of Medicine,
Health Sciences Complex,
Memorial University of
Newfoundland.

FELLOWSHIPS

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London) JUNIOR RESEARCH FELLOWSHIP

Applications are invited for a Junior Research Fellowship (£1,990 p.a. plus approved fees) tenable for 3 years jointly in the Department of Medical Physics for experimental studies in ultrasonic diagnostic techniques. Applicants should preferably have some experience in computer programming.

Applications, with curriculum vitae and the names of two referees, should be sent as soon as possible to Professor H. A. B. Simons, Department of Medical Physics, Royal Free Hospital, Pond Street, London NW3 2QG.

7190(E)

UNIVERSITY OF WARWICK POSTDOCTORAL RESEARCH FELLOWSHIP

IN THE DEPARTMENT OF CHEMISTRY AND MOLECULAR SCIENCES

Applications are invited for a Postdoctoral Research Fellowship to work with Dr D. W. Hutchinson on the synthesis and properties of oligoadenylic acids as inhibitors of protein synthesis. This work, which is funded by the M.R.C., will be carried out in collaboration with Dr I. M. Kerr of the National Institute for Medical Research, Mill Hill, London. The appointment will be for two years commencing as soon as possible. Initial salary will be up to £5,730 p.a. on the Range 1A scale: £3,660 to £6,178 p.a. Applications, together with the names of two referees, should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No. 6/2A/78 as soon as possible.

7161(E)

UNIVERSITY COLLEGE

DUBLIN

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL FELLOWSHIP

IN

PHYSICAL

ORGANIC CHEMISTRY

Applications are invited for the above post to investigate the activating effect of the azomethine function implicated in catalysis by the coenzyme pyridoxal phosphate. The appointment, which is supported by the Irish National Board for Science and Technology, will be made as soon as possible and will be renewable annually for up to three years from October 1, 1978.

Initial salary will be in the range £3,762 to £4,388.

Applications accompanied by a curriculum vitae and names of two referees should be sent to:

Dr R. A. More O'Ferrall,
Department of Chemistry,
University College,
Belfield, Dublin 4.

7202(E)

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

POSTDOCTORAL FELLOWSHIP

Applications are invited for an M.R.C.-funded postdoctoral research fellowship to work for three years on a project comparing and contrasting the protein and glycoprotein composition of myelin and oligodendrocyte membranes from normal and multiple sclerosis nerve tissue. Applicants should have expertise in membrane proteins, glycoproteins and related separative techniques.

Starting salary in the range £3,660 to £4,834 (under review).

Applications should be sent as soon as possible to Dr M. G. Rumshy, Department of Biology, University of York, Heslington, York YO1 5DD, and should be in the form of a curriculum vitae with the names of two referees. Further information can be obtained from the same source. Please quote reference number 11/6094.

7182(E)

STUDENTSHIPS

THE UNIVERSITY OF ADELAIDE DEPARTMENT OF SOIL SCIENCE Applications are invited for a RESEARCH STUDENTSHIP

to support research for Ph.D. with A. R. Dexter of the Waite Agricultural Research Institute on an Australian Oilseeds Research Committee project concerned with the interaction between soil structure and root growth of oilseed crops. Tenure of the studentship depends on continuing support from the Australian Oilseeds Research Committee but at least three years support is expected. The stipend payable is \$A4200 per annum plus allowances for dependants. Some assistance with relocation expenses may be available. Applicants should be graduates with a good honours degree in science subject and an interest in or more of the following would be an advantage: plant growth, soil mechanics, geometry and mathematical modelling.

Applications with a curriculum vitae and the names and addresses of two academic referees should be sent to the Academic Registrar, University of Adelaide, G.P.O. Box 498, Adelaide South Australia, Australia 5001. Closing date October 1978.

7198(E)

SHEFFIELD CITY POLYTECHNIC DEPARTMENT OF BIOLOGICAL SCIENCES RESEARCH STUDENTSHIP

Salary Scale: £2,500 to £3,000 p.a.

Applications are invited for appointment as a Research Student to undertake research into the utilisation of fractions of town refuse in land reclamation schemes.

This work will be carried out in conjunction with South Yorkshire County Council. Applicants should possess a good honours degree in Biological Sciences, Biochemistry or Soil Sciences, and the successful applicant will be expected to seek retraining for a higher degree.

Requests for an application form writing only please to the Recruitment Section of the Personnel Department, Sheffield City Polytechnic (Dept. NA Halfords House, Fitzalan Square, Sheffield S1 2BB. Completed forms should be returned by October 6, 1978.

7177(E)

UNIVERSITY OF LONDON KING'S COLLEGE PHYSICS DEPARTMENT

Applications are invited for a Ph.D. research studentship, tenable for three years from not later than January 1, 1979, for experimental research on the production and properties of cold centres in covalent crystals. The value of the studentship will be at least that of an S.R.C. grant. Further details are available from Dr E. Lightowler, Physics Department, King's College, Strand, London WC2R 2LS.

Help

Our technical services group gets calls all the time from researchers who have found that iodinating proteins can be tricky. We usually have the answers, because at NEN we iodinate proteins ourselves — with our own iodine-125.

Of course, having trouble-free iodine-125 at the outset eliminates some of the trickiness. Ours is the world's most carefully prepared and tested iodine-125.

Each biweekly batch must pass strict tests for radiochemical purity and exact base strength, as well as labeling efficiency in a sensitive lactoperoxidase iodination.

And now the news: We've added a medium concentration, low pH iodine-125. Now you can order any combination of concentration and pH from NEN:

NEZ-033 Standard package
in 0.1-0.5ml
of ~0.1M NaOH solution

NEZ-033H High concentration
>350mCi/ml
in ~0.1M NaOH solution

NEZ-033L Low pH 8-10
High concentration
>350mCi/ml
in aqueous solution

NEZ-033A Low pH 8-10
Medium concentration
100mCi/ml
in aqueous solution

Send for our iodine-125 products brochure.
It tells the whole story.

The Second Translation Kit

From the people who brought you new convenience and reproducibility with the first.

First, Methionine...

Our first translation kit saved you the difficulty of preparing your own lysate for cell-free translation studies, gave you a system free of endogenous mRNA and high in protein synthesis activity, and assured you of components tested for compatibility and reproducible results. All told, it was an excellent excuse to stop cultivating rabbits.

Our second kit does all of the above, too. But, instead of Methionine, L-[³⁵S], the tracer is Leucine, L-[3,4,5-³H]—specially optimized for use with this system. Here's what our Leucine Translation Kit contains:

Rabbit reticulocyte lysate Treated with micrococcal nuclease to inactivate endogenous mRNA and tested to guarantee high protein synthesis activity.

High activity ³H tracer NET-460T, Leucine, L-[3,4,5-³H], >110Ci/mmol. Special lots are prepared and tested for incorporation into protein using this cell-free translation system.

Translation cocktail All the necessary components for proper translation conditions, including buffer, biogenic polyamine, and energizer.

Control mRNA Purified mRNA to check the biological activity of the system.

Salts and sterile deionized water Selected and prepared to minimize potential ionic or enzymatic inhibition of the system.

Instructions for use The protocol is straightforward and includes suggested assay procedures.

So now there are two, and only two, translation kits. Call us toll-free for details on either or both.

When you're studying cyclic nucleotides and you don't know which way to turn

We understand that when you are working in the cyclic nucleotide area, the subject is so diverse and so complex that you don't want to have to worry about the problems of accurate measurement.

So we would like to take a little weight off your mind and offer you our two kits in this field.

Cyclic AMP and Cyclic GMP.

Both of the tests are simple, accurate and will take you about four hours from start to finish.

So it's not surprising that you can carry on with your research and leave the problems of accurate measurement to us.

You know where you are with our Cyclic AMP & GMP kits

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures.

Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).

This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail); 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

28 September 1978

To Geneva yet again

REPRESENTATIVES of the United States, United Kingdom and Soviet Union are back in Geneva this week to resume talks on a comprehensive ban on nuclear testing. Regular readers of these columns could be excused for stifling a slight yawn on hearing this; for many years now it has seemed to us and to others that a ban was just around the corner. Each year we have been reliably advised that the odds were fifty-fifty on a treaty by Christmas, but those who believe that this implies ultimate success should ponder the message of the coin tossed in Tom Stoppard's play *Rosencrantz*—which came down 'heads' more than eighty times in a row.

At present the two superpowers operate a voluntary limit of 150 kilotons on underground tests, and they, along with most other countries, are prevented from firing above ground by the Partial Test-Ban Treaty of 1963. France and China, non-signatories of the treaty, used to test regularly in the atmosphere, but in recent years, they too have gone underground. Although only three countries are party to the present negotiations on a comprehensive treaty, it is hoped that if and when a document is produced it will prove widely acceptable, and even those seasoned non-signers, France and China, will be prepared to adhere to its spirit. It goes almost without saying that many nations under strong pressure not to venture into nuclear proliferation are very keen indeed for some evidence that the superpowers are putting a brake on their own weapons programmes, and a comprehensive test ban, although only a partial dampener on weapons development, has great symbolic importance.

What then holds up a treaty? The traditional reason for delay has been the inadequacy of systems for monitoring compliance, whether by seismic or other means. There has been considerable progress in these matters in the past ten years; further major improvements in the near future are, however, unlikely. Above certain yields the risk of detection and identification is now very high, but below these levels there is more and more scope for undetectable clandestine activity. No technical monitoring system can provide complete satisfaction. Fortunately this now seems to be widely understood; no interested party would now be at liberty suddenly to 'discover' inadequacies in the monitoring system and claim that negotiations had been conducted in ignorance of them.

A more recent obstacle to a treaty has been peaceful nuclear explosions. The almost complete loss of support for these in the United States, on economic and public-acceptability grounds, contrasts with enthusiasm within the Soviet Union, where more than forty such explo-

sions have been fired for a variety of purposes. But even in the Soviet Union the pace seems to have slackened off of late, and elsewhere no one—not even the Indians—now has much enthusiasm. The trouble with peaceful explosions is that there is absolutely no way of verifying that they do not also have a military purpose, and any attempt to exclude such explosions from a comprehensive test-ban would have to be viewed with the utmost suspicion.

Most recently, concern has been expressed in the United States about the effects that a test-ban would have on stockpile efficiency; it is claimed that in the absence of regular testing, devices cannot be trusted indefinitely. This is a controversial matter; not even all those associated with the weapons laboratories would have the same point of view. But there have already been calls for the ban not to be total, but to allow limited low-yield testing. If peaceful explosions could be a vehicle for weapon development, however, so too could ostensible stockpile testing.

So what will emerge from Geneva? It has to be acceptable to the US Senate which ratifies such international agreements, so it will probably err on the side of caution. The Soviet Union seems prepared to forego peaceful explosions, but only for a short period. A limited duration treaty would suit the United States fine, because it would sidestep the question of the future of the weapons laboratories. At a guess there will be a three year ban on the firing of any nuclear devices whatsoever. But do not be deceived; although the treaty will undoubtedly come up for renewal there must be the most serious doubts that it actually will be renewed. Between 1958 and 1961 there was a thirty-four month moratorium in testing but it did not lead to a permanent ban. From public pronouncements in the United States and from an apparent Soviet desire to push ahead on the peaceful uses front, it seems clear that many have already made up their mind that the ban will merely be a temporary measure.

What purpose does a British presence serve at these talks? Undoubtedly it has a certain cosmetic value in dispelling the impression that the two superpowers are colluding, and probably there are technical matters where British representation injects a sensible new dimension. But Britain is so closely tied to the United States in nuclear affairs that it is most unlikely that a truly independent line could be taken. It is probable that the treaty which will emerge from Geneva will be a poor substitute for a truly comprehensive permanent ban; somewhere an independent powerful and respected voice should be saying this. □

Sinai in peace and in war: one plan was to make it an Arab-Israeli "national park"

Israel wants scientific cooperation with the Arabs

ISRAELI scientists see the outcome of the Camp David talks as a unique challenge and chance for mutual cooperation—a result which may, at first, seem paradoxical, since the settlement will mean handing over to Egyptian control one of the most strictly protected conservation areas in the world.

During the 12 years that Sinai has been under Israeli control, environmental restrictions have been so strict that not even a single shell could legally be removed from the beach without special permission. The fragile ecology of the area has been extensively studied, and investigations of the "solar lake", a few kilometres south of the pre-1967 frontier have provided a new concept in the commercial use of solar energy. For this lake has a natural stratification of salinity allowing bottom water temperature to build up to more than 60 °C, without convective heating of the upper layers which remain at approximately 20 °C. Not surprisingly, at the international conference on the application of solar energy held earlier this month at the Technion—Israel's institute of technology—there was a whole session devoted to artificial solar ponds, which, it is hoped, will ultimately be used for electricity generation, desalination of sea-water and for low temperature industrial heat production.

As far as the ecology of the Sinai is concerned, the non-governmental Society for the Protection of Nature, which has maintained three field study centres in the Sinai—at Na'ama, Yamit, and Santa Katarina—is willing to extend to the Egyptians any assistance they may require. Indeed, Professor Amotz Zahavi told *Nature* that several years ago, the society suggested that the Sinai should be made into an "international park for peace" under joint Israeli/Egyptian control.

For some years, said Professor Zahavi, the society has been passing on its findings and ideas on conservation to the Israeli authorities. Now, with the hand-over to the Egyptians, their experts would be willing to stay on at the field centres, working in collaboration with the Egyptians for the sake of conservation. Professor Zahavi stressed

that the Israeli teams have no idea how the Egyptians will react to this proposal. "So far as we know, conservation is not yet very well developed in Egypt," he said, a further reason why his society is so concerned to help.

Israel has an impressive record in desert reclamation and the cultivation of marginal lands. With perhaps one-third of the world's cultivable land threatened with desertification, Israeli environmentalists describe as tragic the Arab walk-out from last year's conference on desertification when an Israeli delegate rose to speak.

At Haifa, the Kogan-Rose desalination pilot plant, which uses a counter-flow system to eliminate the need for expensive copper-tubing heat-exchangers, has proved its worth, and plans are underway to construct a full-scale installation capable of delivering some million cubic metres per day. The main question to be decided now is where to build it. While such questions are, of course, matters for the politicians to decide, Professor Abraham Kogan, the designer, speaks of a possible joint Israeli-Egyptian venture.

Indeed, the consensus of Israeli scientific opinion seems to run ahead of the formal political situation. Last summer, in his report to the international board of governors of the Technion, made on the occasion of the 30th anniversary of Israeli independence, the Technion president, Amos Horev, stressed that technological co-operation "could well be put into effect with Arab neighbours even in advance of formal peace". Ecologists and technologists are already looking hopefully towards other frontiers. The Dead Sea potash works, for example, which produces fertilizers from evaporated Dead Sea brines, must use a certain amount of non-saline water in the extraction process. With a growing world demand for fertilizer and a virtually inexhaustible supply of raw material, it is small wonder that some engineers think longingly of the fresh water supply, just across the Jordanian frontier, which in British Mandate times was actually piped to the forerunner of the present potash works (then sited at the northern end of the Dead Sea).

Jordan is known to be considering a potash works of her own—a joint development would be more economical and also a powerful factor in the continued peace of the area.

Likewise, marine ecologists in the Gulf of Aqaba stress that however carefully they monitor the tankers discharging at the Eilat oil terminal, the gulf is narrow, and has no real tidal scour. A joint protection and monitoring programme involving all the littoral states—Israel, Jordan, Saudi Arabia, and Egypt—is the best hope of avoiding major pollution in this part of the gulf.

And, looking even further ahead, Professor Y. Avnimelech of the Kinneret water research project even mentioned the old Johnstone plan of Mandate times, by which the river Yarmuk would be diverted into Kinneret, the augmented waters of which could then be used for the benefit of what now constitutes both Israel and Jordan. Since the Kinneret now serves as the sole fresh water source for Israel's national water grid, and the Israeli water economy is so tight that brackish and waste water irrigation is an increasing necessity, even the most academic allusion to such a scheme reflects a considerable commitment to the idea of cooperation.

Such a commitment, however, is more than a pipe-dream of a few scientists, however far ahead the realisation may be, the Israeli government undoubtedly endorses the underlying principle. Addressing the international congress of ecology, which was held in Jerusalem during the week of the Camp David talks, Mr Yigal Yadin, the Israeli deputy prime minister, stressed that "ecology has no national boundaries". After outlining Israel's considerable achievement in developing the country without major ecological damage, while at the same time extending aid to such third world countries as would accept it, he concluded—"We are yearning for peace so that we can strive for a better world. Let us endeavour when peace comes on earth—if the earth still be there—we may be more worthy to enjoy it".

Vera Rich

Argentina: concern over continued disappearances

On the eve of the Twelfth International Cancer Congress in Buenos Aires, **David Dickson** reports on the fate of 15,000 missing Argentinians, many of them scientists

Two weeks ago Dr Lepanto Bianchi, an Argentinian orthopaedic surgeon, was arrested and taken from his office by men who claimed that they were from the federal police force. Dr Bianchi's arrest follows the similar disappearance last month of Beatriz Perioso, president of the Argentine Federation of Psychologists, who was taken away from a child care centre at which she had been working.

No news has since been received of Dr Perioso's whereabouts, nor whether any charges have been made against her. And neither has any information been received about two other psychologists, Arturo Smith and his wife Celia Kriado, who were taken from their home the following day.

The American Psychological Association has written to the Argentinian President, General Jorge H. Videla, requesting information about the situation of the three psychologists, but no reply has been received.

Professor freed

Meanwhile, however, the Argentine authorities last week released Dr Claudio Bermann, a former professor of psychiatry at the University of Cordoba and director of a psychiatric clinic, who had been arrested and held without specific charges since April 1976.

A number of foreign institutions, including Amnesty International and the US National Academy of Sciences' Committee on Human Rights, as well as the Buenos Aires-based Permanent Assembly on Human Rights, had pressed the Argentine government for his release. Last week he was given permission to leave the country, and flew directly to Israel.

In August Elena Sevilla, a research physicist at the Universidad del Sur in Bariloche who had been arrested in November 1975 in hospital shortly after giving birth, was allowed to leave the country after similar moves had been made on her behalf and is now in the US. However in the same month the Permanent Assembly was notified of 11 more "disappearances", and suspects the actual figure may be four or five times this number.

A number of scientists are planning to raise the issue of human rights at the Twelfth International Cancer Conference, which begins in Buenos Aires next week, and is expected to be attended by 7,000 scientists from all over the world.

The National Academy of Sciences, following a visit to Argentina earlier

this year by three representatives of its committee on human rights, decided not to endorse a proposed boycott of the meeting by US scientists. However the committee agreed to assist "those Congress attendees who so desire to express their human rights concerns while in Argentina," primarily through supporting the activities of the human rights clearinghouse of the American Association for the Advancement of Science.

A number of those attending the conference are planning to hold regular caucus meetings on the human rights situation in Argentina. And facilities are also being made available to provide conference delegates with information about the current situation by the Permanent Assembly.

Conference officials point out that the high expected number of participants indicates that moves to boycott the conference—a parallel conference, for example, is being held in Paris under the sponsorship of Professor Andre Lwoff, and is expected to attract several hundred participants—are likely to have relatively little impact on the Buenos Aires arrangements.

Other Argentine scientists have publicly objected to the "pernicious propaganda" which they claim is being spread about the current situation. "At present, the universities and research institutes are places of quiet and fruitful work, in contrast to the agitation, the activism and the persecution of professor and scientists that were so frequent before March 1976 [the date of the military coup]", according to two members of the Buenos Aires National Institute of Medicine in a recent letter to science.

Academic asphyxia

The Permanent Assembly, which brings together various Argentinian groups concerned with human rights, sees the situation slightly differently. "In the national universities, if a climate of perfect order rules, it has been achieved at the cost of the virtual extinction of all interchange of ideas, and similarly the elimination of the whole of a vast cultural sector whose political ideas do not coincide with those of the university authorities," the assembly says in the most recent report on its activities.

"This situation has brought about a noticeable impoverishment of the academic level, generating a dangerous climate of academic asphyxia," according to the assembly's third commission,

which is responsible for the areas of culture, religion, the arts, the sciences, the professions and technical fields.

Earlier this year the assembly published in the Buenos Aires newspaper *La Prensa* a list of 2,500 names of individuals who had disappeared since March 1976, and whose current whereabouts were unknown. A further 500 cases were reported to the assembly after the advertisement appeared, and officials estimate that they have only been informed of one-fifth of those who have disappeared, giving a total number of 15,000.

Many killed

It is feared that up to half of these—men, women and children—have been killed. In addition, it is estimated that there are 8,000 political prisoners being held in Argentine goals, at least half of whom have not been through a proper judicial process.

Scientists figure prominently among those who have disappeared or been imprisoned, particularly those previously involved in organisations such as the now-defunct Argentine Physical Society, which had taken an active part in debates on political issues in the period immediately before the military coup of 1976. However, other scientists who have disappeared or been imprisoned have, it is claimed, played little part in political activity.

Over 2,000 scientists, including both university teachers and research workers, lost their jobs when the military government came into power. Many have since left the country: "the low salaries, added to the lack of security, threats, and the lack of an adequate scientific programme, has motivated the exodus of a great number of scientists and professionals," according to the assembly's report.

Some Argentinian scientists who remain are also concerned at the low priority given to education in the national budget. "In the early 1960s, expenditure on education represented about 20 per cent of total government spending; now it is down to 8.3 per cent," according to Professor Jose Westerkamp, a nuclear physicist at the University of Buenos Aires.

Some areas of research, such as nuclear engineering, still flourish. But in many fields of more basic science, the combined lack of professional manpower, adequate funds, and postgraduate students has resulted in a dramatic decline in activity. □

US scientists in new row over cancer at work

PREVIOUS studies of the incidence of cancer associated with occupational exposure to toxic substances may have seriously underestimated the true extent of the problem, according to a statement issued last week by three of the US National Institutes of Health.

Such studies had tended to estimate that the incidence of cancers which would be associated with occupational exposure was between 1 and 15 per cent. But they had been flawed by factors such as the failure to take into account the latency period of several decades that may occur between exposure and the appearance of a cancer, or the synergistic effect of exposure to several carcinogens, the statement claims.

Extrapolating from the results of recent studies of asbestos workers, it concludes that "there is nothing in the gross cancer statistics for the US population which is inconsistent with the hypothesis that up to 20-40 per cent of all cancers are (or will be in the next several decades) attributable to occupational factors".

Those who have contributed to the statement include Dr Arthur Upton, director of the National Cancer Institute, and Dr David Rall, director of the National Institute of Environmental Health Sciences, as well as

PVC production: dispute over hazards

eight other scientists from these two institutes and the National Institute for Occupational Safety and Health.

To offer a figure for comparing the risks from exposure to various industrial compounds, the statement chose "excess cancers" associated with each. (This quantity is defined as the product of the exposed population, the age-adjusted incidence of cancer and an adjusted risk ratio.) The number of annual excess cancers associated with asbestos is then 13,900, but several other substances have excess numbers almost as high: arsenic, 7,300; benzene, 1,400; chromium, 7,900; nickel oxides, 7,300; and petroleum products, 9,100.

The statement predicts that in the years ahead, cancers caused by exposure to other substances will also begin to rise sharply. "The five other agents together pose hazards similar to or greater than those posed by asbestos," says the report. "If only one of the thousands of chemicals introduced into commerce in the past 30

years proves to be as hazardous as asbestos, this could suffice to maintain comparable rates of occupationally-related cancer for decades into the future."

Several industry scientists refused to comment on the report until they had had several weeks to analyse the data. However the President of the Society of the Plastics Industry called the statement "an embarrassment to medical science". He cited a section of the report that predicted 1,940 excess cancer deaths a year to exposure to vinyl chloride as evidence of faulty methodology. "The facts show clearly that vinyl chloride is hazardous to man only at high levels of exposure and over relatively long periods of time", he said. The levels of population considered at risk by the statement are much too high, he concludes, saying that only 23 cases of cancer caused by exposure to vinyl chloride have been confirmed in the last 16 years.

The statement, which is based largely on a number of individual studies carried out by various of its authors, was used by Health Secretary Joseph A. Califano as the basis of a speech earlier this month to a national conference on occupational health organised by the American Federation of Labour-Confederation of Industrial Organisations (AFL-CIO).

In his speech, Dr Califano said that the results were "alarming", and that they would lead to an increased emphasis by the administration on the prevention rather than the cure of cancer.

John Douglas

Radio back-up in rural health service

A VHF communication network is now operating in the rural area of Ballabgarh, 35 kilometres south-east of Delhi. The project is an experiment to see whether such a system is an economic and effective way of providing health care for India.

The network was planned and set up by the Information, Planning and Analysis Group of the Electronics Commission for the All India Institute of Medical Sciences which is running a Comprehensive Rural Health Service Project at Ballabgarh, providing health services to the local community and teaching medical and paramedical staff.

The VHF network consists of four 15-watt fully transistorised transceivers—three fixed and one mobile—and one 400-mW walkie-talkie set. The fixed transceivers are at Ballabgarh Referral Hospital and two primary health centres and the mobile transceiver in a hospital van. The walkie-talkie set is provided to health workers during visits to patients in villages to communicate

with the main hospital. The network covers 368.64 square kilometres and a population of 100,000.

In India, where the majority of people live in villages, health centres are widespread with no telephone links between them. Information about both routine and emergency cases has to be delivered by hand and may often arrive too late to be of any use. A communication network between health centres is therefore seen as essential for effective health care in rural areas, and a VHF communication network is a novel move. The cost-effectiveness has yet to be established. For this purpose, each call made or received from a station is recorded and medical case histories connected with each call pursued to find out the usefulness of the network in treating the patient. If the project proves its worth, its scope could be enlarged and the Ministry of Health and Family Welfare will be asked to establish similar networks in other areas.

Zaka Imam

Scepticism over Soviet promise to let Levich go

FRIENDS and colleagues of Veniamin Levich have greeted with guarded enthusiasm the news that he may shortly receive a visa to emigrate from the USSR to Israel. This is not the first time the 61-year old Academician has been promised an exit visa.

This time, however, the situation seems more auspicious. The announcement of a visa for Levich and his wife, as well as for 17 other families of Refusniks, was made by US Senator Edward Kennedy after his recent visit to Moscow, during which he had talks with Mr Brezhnev.

It seems likely that the current promises are designed to alleviate western reaction to the recent wave of 'human-rights' trials in the Soviet Union. Senator Kennedy himself stressed that the granting of the promised visas would improve international relations. Until the Levichs actually arrive in the West, however, the possibility still remains that this promise is nothing more than a diplomatic gambit in the cause of paper detente.

Science: a means of locating resources

SOMETIMES I fear that we may lose sight of a few realities when we relate science and technology to development. We must be a little guarded, in case too much of the burden for economic development and advancement of countries be placed on the shoulders of science and technology, as a result of which it will be blamed for the failures which will inevitably occur. Science and technology cannot provide, in themselves, the motivation necessary for development. This lies with the political will and in the social drive of the individuals and communities of a country, both in recognising their opportunities and realising them.

In demonstrating that science and technology are nevertheless critical for development, I will limit my comments to economic development. This is not to ignore the social and cultural aspects, or minimize their significance, but because they require a rather different approach. Nor am I concerned, herein, with the current questioning of the value of economic development, as this can too easily generate only social palliatives instead of pragmatic solutions to poverty and inequity, and result in calls for the simple redistribution of wealth at the cost of increasing it overall. It is a separate issue.

The purpose of economic development, is, by and large, the increase in the production of wealth; and the production of wealth takes place by the application to natural resources of man's labour. Under natural resources, I include not only all natural phenomena and associated resources, renewable and non-renewable, transformable and non-transformable, but also the land itself. These are not the product of man. Labour, in this context, is the effort by man which arises from the application of his hands, brain and the tools which his brain has shown him will increase his efficiency. Thus, wealth is the product of man and his resources, which, obvious as it may seem, is often forgotten, as one too frequently reads of natural resources or human resources being regarded as wealth by themselves. The same applies to the scientific and technological capacity of a society. The point is important because loose thinking on it confuses the issues of the production and distribution of wealth and leads to a loss of objectivity in economic development and the assistance which

By
Hiroshi Harada
Deputy Assistant
Director General
for Science, Unesco

science and technology can offer it.

The relationship of science and technology to the production of wealth can be seen once it is recognised that a natural resource is no use until it has been found, described and understood. Science, to an increasing degree, is the identifying process in bringing resources into the production of wealth. Technology, however, is related to labour, and the level of technology possessed by labour is the index of its efficiency. Given unlimited natural resources, wealth may be increased without improvement in technology, but with limited natural resources technology must be improved.

This provides a degree of distinction between many developed and developing countries. In general, the former have increasingly to develop their technological capacity, whilst the latter have, for the most part, still to ensure that their natural resources have been identified scientifically and fully realised economically.

It is important to determine, therefore, if the balance demanded between science and technology is, for any country, the right one in relation to its stage of development and knowledge of its resources. There is a real danger that the cart is being put before the horse: that the developing countries are trying to launch into advanced technologies without an adequate economic justification, when they should still be seeking to upgrade their scientific capacity for its tasks both

of inventory taking and application to renewable resources. Technology is a requirement of circumstances, not an economic paracea. The 'technological gap', as it is called, is as much a reflection of the different needs of countries as it is of restrictive practices, justifiable or otherwise.

The situation must also be seen within the time and circumstances within which it occurs. It has been noticeable that, particularly in countries which in the last decade or so have divested themselves of colonial rule, there has been a decline in the output of the scientific establishments responsible for natural resource inventories and improvement of the yields from renewable resources. This has arisen because of the need of these countries to establish or strengthen their capacity to train their own scientists.

This is a major task, the priority for which has inevitably drawn scientific and technical manpower into the universities, often with better conditions and facilities than exist in the much older applied science establishments. Only now does one see the newly-trained manpower beginning to refill them. It will need more time before able scientists will seek opportunities in industry and only then if its productive capacity and size will sustain viable research and development departments. It is at this stage that the transfer of advanced technologies will really become significant, not only because of the need, but also because there will be an adequate indigenous scientific capacity not only to seize and adapt it, but also, and perhaps more important, to create it.

I think, also, that it is a well to remind ourselves of the basic differences between, and the origins of, science and technology. There seems to be a tendency for administrators, in particular, to regard them as being

Resources: science discovers them, technology applies them

This is a shortened version of a paper presented to a recent meeting on UNCTD convened by the World Federation of Scientific Workers. The full paper will appear, along with others, in the Report and Documentation of the conference currently being prepared by the Federation.

largely similar in quality and thus to be mutually interchangeable and competitive on the same terms. The development of the so-called applied sciences has further tended, in providing a link between the two, to blur the issue. The result has been, I feel, an over-emphasis on the need for science to justify itself in the same way as does technology, and to have an immediate, direct and finite impact on socio-economic problems. Many scientists have subscribed to this, even if unconsciously, in the search for support for their activities. This too often leads to a shortfall in promises regarding its utility in the eyes of administrators and further strengthens their doubts about the efficacy of science compared to technology.

Science, or demonstrable knowledge, is open-ended and has a separate existence. It can be pursued for its own sake, having a cultural value as deeply felt and satisfying as that resulting from the study of art or the humanities, while still serving to relieve man's condition. Technology, in its usually accepted sense, has no existence separate from the material production in which it is involved or for which it was created. Science starts with man's basic curiosity about his environment; whereas technology starts with man's basic economic urge to carry out more easily or profitably a productive activity.

Science, almost by definition, is non-existent until it has been communicated (transferred) to others. Technology has its proof in its products and, therefore, needs not itself to be transferred, thereby conferring rights to its personal ownership and a truly commercial value. Its 'excellence', if I may apply the term, is self-evident. Science, however, needs to be patronised, because its value and excellence is not readily apparent, particularly to administrators. They have to monitor its achievements and excellence, particularly in its more basic aspects, through scientists; and this has, and always will be, an act of faith on their part, which is not a basis for resource allocation they like, particularly since the demand has reached the level it has, today.

Science and technology have been joined in modern times only because much advanced technology has to be science-based; it is now more often manufactured in research and development departments than invented by simple intelligence and manual skill. This, however, does not alter the nature of science and technology, although it does increase the role of science in the production of technology and further emphasises the need for its development.

This brings me to my main point for developing countries, which is that in seeking economic and technical inde-

pendence, particularly in decision-making, they must strengthen their scientific and engineering cadres, not only in their numbers and disciplines, but also in their excellence and problem-solving ability, which latter is the first step to the provision of a genuine indigenous technological capacity. This requires the dynamic teaching of science from the secondary levels of education, through inspired guidance of senior students at the university level, to strictly disciplined research work at the post-graduate level. It means fostering scientific societies, both learned and professional, and the establishment of a stable corps of scientists large enough to be viable and self-critical. It involves increasing considerably the number and quality of

the technical cadres, because most developing countries are characterised by poor ratios of technicians to scientists, which means that any technological improvement or change the latter may prescribe cannot be widely applied.

All this takes a long time and there is no short cut, least of all that based on too early attempts to introduce technologies for which the indigenous technical capacity to handle it is inadequate or absent. We have already seen the mistakes resulting from trying to introduce the applied sciences before the basic sciences are adequately established. To repeat the error in respect of advanced technologies is a greater mistake and can mean an even more extended thralldom, through expensive patents and licenses, to technologies created originally for developed countries.

Moreover, if it is the contention of many developing countries, as it seems to be, that many of these technologies are inappropriate, for whatever reason, technical, economical or social, then it is an even more self-defeating choice as a way to indigenous development. And, it carries with it the threat of limiting the resources for indigenous scientific effort and, thereby, the exploration for, and discovery of, the natural resource potential of a country, which again brings me back to the point I made earlier, namely, that I

believe many of the developing countries need to complete their natural resources inventories before launching into an era of high technology.

I feel that for the realisation of UNCSTD's primary purpose, which is the strengthening of the indigenous technological capacity of countries, that we must think not only of the problems of the choice and transfer of technology but also of the establishment of the right balance between science and technology for development of any country.

Although Unesco's own responsibilities are primarily concerned with the promotion of, and international cooperation in, the natural sciences, whereas other UN agencies have the prime responsibilities for these in the applied sciences, Unesco has increasingly emphasised the important role of natural sciences in relation to the identification and development of the natural resources of developing countries. It is still concerned about the inadequacies both in policy-making in this field and in the creation of effective manpower resources to implement the policy.

In respect of the transfer of technology, Unesco recognises that the problem is much more complicated than that posed solely by the difficulties of gaining access to a particular technology. It involves the creation of a technologically-minded community, not only at the higher levels of specialisation but also at the lower levels of comprehension, where standards and excellence of technical handling are essential for the development of a genuine indigenous capacity which can respond to the needs and opportunities presented to it. Without the development of this basic ability, the transfer of technology alone will remain unfruitful in the long run and tend to separate the communities involved.

For both these reasons, Unesco still stresses the importance of the role of education as one, at least, of the technical prerequisites for strengthening the scientific base of a country and for the successful importation and application of technology. It is, of course, not the only prerequisite. There are social and environmental constraints involved also in the transfer of technology and Unesco has developed programmes in these two fields to examine them and discuss the socio-cultural conditions likely to foster indigenous development processes.

Unesco's activities in this matter of science and technology for development, however, are limited by the availability of funds and the degree of international cooperation it can obtain. We hope that UNCSTD will urge the Member States to be more generous and far-seeing in both these. □

A massive particle conference

from Frank Close

THE most massive subatomic particle ever discovered was found at Hamburg just one week before a thousand physicists from all over the world gathered in Tokyo for the biennial conference on High Energy Physics. It is the first time that this series of conferences, which began in 1951, had ventured outside of its USA, west-European, east-European cycle. The excitement that has been generated by the discoveries of the last four years has created much cultural interest in the Far East in this most fundamental field of physics, and a delegation from the People's Republic of China was attending such an international gathering for the first time.

The message from the conference was clear. The rapidly accumulating data of the past two years have confirmed our suspicions as to the picture on Nature's jigsaw. The pieces have begun to fall neatly into place and an elegant portrait is emerging.

Unifying the natural forces

The electromagnetic and weak interactions are indeed unified in the "simplest" way, the $SU_2 \times U_1$ model of Glashow, Weinberg and Salam. Briefly, there is much evidence supporting this, and no high energy data that go against it.

To accomplish this unification, Nature has a set of fundamental fermions (quarks and leptons) and has ordered them into left-handed pairs. For leptons we know now that three such pairs (or "generations") exist (*News and Views* 271, 406; 1978): electron and neutrino; muon and a second neutrino, τ and a third neutrino. The existence of the third pair has been firmly established only in the last year. For quarks two generations are well-established. The up and down quarks (found in the proton) have been known for many years, whereas the second generation of strange and charm quarks were established when charmed particles were discovered just before the previous conference in this series (*News*

and *Views* 262, 537; 1976).

Evidence was presented to the conference that a fifth quark (bottom, b) exists. A sixth quark is confidently predicted to complete the third generation of quarks. There is optimism that the advent of PETRA, the new electron-positron colliding beam facility to be opened in Hamburg this month, will provide evidence for this sixth (top, t) quark before the next conference in this series.

The leptons interact by exchanging photons (familiar QED) and also W^+ , W^- and Z^0 "weak gauge bosons". These must be found to really confirm the model. They are predicted to have masses around 70-90 GeV and so we have to be patient for about three years. A session on future accelerators discussed the new machines under plan that may find these objects, and also reviewed the ideas for machines to be built around the world in the longer term and the profound questions that may be asked of them.

The quarks also interact with the above bosons. In addition, quarks carry a quantum number called "colour". New evidence supporting this was presented at the conference: τ decay rates; electron-positron annihilation rates at low energies from Frascati and DCI, Orsay, and the production rates for lepton pairs in proton interactions etc. The quarks can then interact by exchanging coloured gluons. This leads to a theory called "quantum chromodynamics" or QCD (these gluons of QCD are analogues of the photons of QED), and as such provides a theory of the strong (nuclear) interaction.

One consequence is that the scaling phenomenon seen previously in deep inelastic scattering of leptons on proton targets should be violated in a systematic way. In 1976 qualitative support for this prediction was known. It appears that quantitative support is at last emerging now that the older electron and muon scattering data are being supplemented by neutrino interaction data at Fermi Lab. and, in

particular, at the CERN SPS in Geneva. This facility became operational in 1976 and the high precision data that it has provided have been instrumental in establishing the weak-electromagnetic unification and are now testing the QCD theory of strong interactions.

Although the emerging data in lepton and in hadron interactions are all consistent with QCD, no conclusive tests that would confirm or deny the theory are yet available. Theorists are still uncovering some of the rich subtleties in the theory and there was much discussion as to the understanding we have of the theory and what we must do to really test it in a severe way.

Heavy leptons

At the 1976 Tbilisi conference the existence of a heavy lepton (τ) was controversial. In the two years since then its existence has been established beyond any doubt by a series of experiments at Stanford (SPEAR) and Hamburg (DORIS). These have made precise measurements of its properties; e.g. its mass is known to be within 0.5% of 1785 MeV (almost the mass of the deuteron!).

All the data suggest that the τ decays by weak interactions producing a (massless?) neutrino and that parity is violated in the process. It indeed appears that just as the electron and a neutrino (ν_e) are brothers in weak interactions (e.g. the radioactive β -decay of the neutron into proton, electron and ν_e), and that Nature repeated itself with a second pair (muon and its neutrino ν_μ), so now we have clear evidence that there is a third generation of leptons, the τ and its neutrino.

Each of these generations violates parity in weak interactions in the same way. It seems that each generation is identical but for two things: the τ is much heavier than the muon (100

F. E. Close is in the Theory Division at the Rutherford Laboratory.

MeV) which is in turn much heavier than the electron (0.51 MeV); just as the muon does not transmute directly into an electron (*Nature* **266**, 679; 1977) so the τ does not directly turn into electron or muon.

The data on the τ decay patterns seem to be consistent with the above properties of the τ : decays which should not be seen indeed appear not to be there and decays which should be seen are found. In particular a problem with $\tau \rightarrow \pi + \nu$ (*News and Views* **271**, 407; 1978) has now gone away: the decay is seen at the expected rate.

Heavy quarks

Having at last established the existence of three generations of elementary leptons (*News and Views* **271**, 407; 1978) attention has turned to the questions of whether there is indeed a third generation of elementary quarks.

In the summer of 1977, the Y (up-silon) particle, 9.4 GeV in mass, was discovered in muon pairs produced by proton-proton collisions at Fermilab (*News and Views* **271**, 407; 1978). At the conference it was reported that the Y had now been seen by an independent Fermilab group and also by three groups working at the CERN Intersecting Storage Rings in Geneva.

The real excitement was provided by the groups working at the electron-positron colliding beam machine (DORIS) at Hamburg. It was reported a month ago (*News and Views* **273**, 705; 1978) that the Y had been directly produced in electron-positron annihilation, with properties suggesting that it was a bound state of a fifth flavour of quark (bottom) and its antiquark. Just a few days before the conference, the DORIS groups managed to produce a heavier version of this state (Y') with a mass of 10.01 GeV. Measurement of its coupling strength to photons and comparison with the group's data on the lighter Y were discussed and seem to indeed confirm that these are bound states of a bottom quark.

This precise mass determination was communicated to the group at Fermi Lab who had earlier found the Y in their proton experiment. They do not have the precision of DORIS but their data had shown an enhancement smeared out over 9 to about 10.5 GeV in mass which suggested that two or possibly even three Y -like particles were present. Now that the masses of Y and Y' were known so precisely they were able to look again at their data and found that it indeed requires the existence of a third Y (Y'') with predicted mass of 10.38 GeV. This discovery was telephoned to Tokyo with the recommendation that scientists at DORIS do a high precision search "between 10.379 and 10.381 GeV!".

This may turn out to be one of the first discoveries to be made at PETRA, the new higher energy electron-positron machine opening in Hamburg this month. What is interesting here is that only two Y states exist below charm production threshold and it had been predicted that three Y states should exist below bottom production threshold. This verification created much excitement for the PETRA programme since if the top quark exists (completing the third quark generation) then it will be much heavier still with the result that several θ states—bound states of top quark and antiquark—should exist below top production threshold. This gives the prospect of detailed investigation of quark dynamics by studying transitions among these levels of "toponium" analogous to transitions among levels of positronium and hydrogen in atomic physics.

The Hamburg group has studied the decay products of the Y . They have a different angular distribution than the particles produced in the electron-positron annihilation at energies just away from the Y resonance. This is precisely as predicted by QCD. However, it is not yet possible to be entirely sure that the effect is due to QCD as against random filling up of available phase space. This will become clear when the θ ("toponium") is found since at extreme energies the QCD theory predicts angular distributions quite unlike random phase space.

Future prospects

An experiment from Fermilab was reported that shows that particles containing b quarks are not stable, which implies that b quarks decay weakly. Decays of quarks in one generation producing quarks in another generation are familiar (*News and Views* **266**, 301; 1977) and are accommodated by the Cabibbo mixing theory. The decay of the b quark implies a new Cabibbo-like mixing involving the third generation with first or second generations. Weinberg stressed that (barring an accident) this necessarily leads to CP violation and hence one of the great puzzles of physics may be about to be solved. Indeed, such a theory of CP violation was postulated by Kobayashi and Maskawa in Japan as long ago as 1972. An important experimental programme will be to study the properties of b decays to see if they are quantitatively in accord with the magnitude of the CP violation which is known to exist.

If these expectations are all verified, then will this be the end of physics? Weinberg highlighted some of the remaining profound questions. Can we unify the strong with the weak and electro-magnetic forces? (some ideas

here were reviewed by Salam). Can we understand the various dimensionless parameters that pervade our universe, like the fine structure constant α , ratios of lepton masses and quark masses; the magnitude of the Cabibbo quark mixing angles and the weak-electromagnetic (Weinberg) mixing angle. The conjecture was that these answers may come as a consequence of a successful grand unification of the natural forces.

Lurking in the background was gravity. Grand unification may take place at energies like 10^{16} GeV (the Planck mass) and the reason for there being distinct forces with different strengths in our current experience may be due to the present coolness of the universe. So how might we achieve this grand unification? Weinberg revealed his ideas—a blank transparency. □

Echinoderm biology

from David Nichols

Two international meetings devoted entirely to echinoderm biology have taken place this year: in March, the Third International Echinoderm Conference was held at the Australian Museum, Sydney, and in July a meeting was organised principally for European workers at Bedford College, London.

At both meetings this year, the proportion of papers offered on the various groups of echinoderms was remarkably similar: notably, about a quarter at each were devoted to starfishes, and a tenth to palaeontological aspects. A major difference in the coverage was that at Sydney about a quarter of the papers were taxonomic, reflecting perhaps the present concentration on this type of work in the Australasian area, while in London only a single paper (by an Australian) was taxonomic.

It would have been all too easy for the Sydney meeting to have been dominated by papers on the coral-devouring Crown-of-Thorns Starfish, but the convener, F. W. E. Rowe (Australian Museum), wisely rationed this subject to three papers. One of these referred to the possible cyclic occurrence of population explosions in this starfish. Elderly fishermen have said that they recall abnormally large numbers of *Acanthaster* being present on the Great Barrier Reef at about the turn of the century, and E. Frankel (University of Sydney) has examined cores taken from the reef talus in several areas to see if he can identify abnormally high concentrations of the disarticulated skeletal ossicles of this starfish among

the broken coral and other material through the cores. He has assumed that the relative occurrence of these ossicles at the various levels in the cores might reflect the relative abundance of the starfish at the time the debris was being abraded from the reef. So far, Frankel has gone back 900 years, and, while not yet recording evidence of a plague 70 or 80 years ago (at the turn of the century), he has recorded higher-than-normal incidences of remains of *Acanthaster* at 110, 185 and 450 years BP.

The conveners of the London conference accepted two papers on *Acanthaster*. First, R. G. F. Ormond (University of York) described a computer model for the population strategy of the starfish, based on data from studies by the Cambridge Coral Starfish Research Group in the Red Sea. The model showed, for instance, that a rise in ambient temperature of a mere 2 °C could produce a population explosion from the 'background' level of 10 to 25 animals per kilometre of reef front to plague proportions of 130 or so. This suggests that *Acanthaster* may lie somewhere near the centre of the r-K strategy spectrum (in MacArthur and Wilson's terminology), and it may vacillate between low and high population levels, as suggested by the periodic plagues shown by Frankel's data.

The second paper on this animal was by J. Vasserot (Station Biologique, Roscoff, France) who suggested that a useful method of control in times of plague might be the use of hypersalinity, which he has found effective against the large European starfish, *Marthasterias*. The method consists of spreading common salt crystals over the aboral surface, and the treatment, which is non-polluting, results in death in a few days. In discussion after this paper, a contributor remarked that this method is already in use by Dutch shellfishermen, who transfer growing mussels from mussel-beds to the holds of their ships, subject them to high salinity, then return them to the beds. This treatment is apparently effective in killing starfish predators adhering to or hiding among the mussels, but does not kill the mussels themselves.

At one time a possible biological control of the Crown-of-Thorns was suggested, which involved seeding the infested reefs with a shrimp, *Hymenocera*, which was known to attack starfishes by piercing the body wall and extracting coelomic fluid. The method was not successful, but it focused attention on the relationship between shrimps and echinoderms. It later began to emerge that such associations are more commonly symbiotic or commensal than predatory. At the Sydney meeting, A. J. Bruce (Director, Heron Island Research Laboratory, Queensland) gave a survey of such associations

in the Indo-West Pacific region, and estimated that about 11% of known shrimps in these waters form some sort of association, mainly with starfishes, sea-urchins and feather-stars. Many use the host merely as a retreat, and emerge on to the substrate to feed; sometimes there may be as many as 50 shrimps on one host; colour patterns in a single species differ according to the host and are often highly cryptic; diurnal colour change has been observed; and some shrimps shave a sea-urchin of some of its spines to make a 'clearing' in which to reside. Little is yet known of these associations, clearly a rich field for future work.

Still with interspecific associations, a highly unexpected spin-off came from some conventional studies of reproductive cycles in the common Australian cushion-star *Patriella exigua* by D. T. Anderson and C. Lawson-Kerr (University of Sydney), this time between the starfish and a terrestrial caddis-fly. *Philaniscus* is a caddis that is known to inhabit the littoral zone in Australia, but until now its intermediate host has been a mystery. During routine sectioning of the gonads of the starfish, these workers observed some egg-strings that clearly did not belong to the starfish, and these were subsequently identified as belonging to the caddis-fly. The female fly was later seen to settle on the dorsal surface of the starfish at low tide and penetrate the dorsal integument in the region of the gonads with a long ovipositor. As yet, the emergence of the young flies has not been observed. This must be one of the very few examples of echinoderms used as intermediate host to a terrestrial organism.

At both meetings there were papers on one of the most controversial aspects of the present-day study of echinoderms, namely, the interpretation of the structure and relationships of a group of fossils variously called carroids, homalozoans or heterosteles. Most echinoderm biologists interpret the unusual fossils in purely echinoderm terms, with a flexible plated body pierced by the usual echinoderm orifices and with various appendages protruding from the body for fixation or feeding. However, in the late 1960s R. P. S. Jefferies (British Museum (Natural History), London) produced a new interpretation of them in mainly chordate terms, referring to them as calcichordates on account of their calcite skeletons. At the London meeting, Jefferies showed how he views both echinoderms and chordates as descended from an ancestor that had settled on the right side of the body (the dextiothetic condition). The calcichordates were seen as the primitive chordate descendants and included forms regarded as primitive cephalochordates, tunicates and vertebrates.

He proposed the term Dextiothetica for the echinoderms and chordates together. The most primitive calcichordates were remarkable in having gill-slits on only the left side of the head, and he pointed out that in the development of the living primitive chordate *Amphioxus* there is a comparable stage with left gill slits only. Jefferies explained this as a straightforward case of Haeckelian recapitulation.

This view has not yet won general acceptance, and at the Sydney meeting G. Philip (University of Sydney) gave a short critique of what he saw as the main points of conflict between the two principal views of these animals. For instance, the 'chordate' school, principally Jefferies, sees the projecting structure of cornutes such as *Cothurnocystis* as a propulsive organ, complete with ossicles ventrally with large muscles above them which were roofed over by immoveable plates; the same structure is seen by those who view the animals as echinoderms as a typical feeding ambulacrum, complete with groove for radial nerve and water vessel, cups for the origin of tube-feet and openable coverplates for protection, very much like an arm of a modern sea-lily or brittle-star. There is clearly a wide divergence of view on the interpretation of these animals, and the hope was expressed in discussion after Philip's paper that the next International Conference should devote a session to this one topic. Much rests on the presumed occurrence of certain types of soft tissue adjacent to the fossilised hard parts that now remain, and perhaps research now underway in Exeter on the nature of the calcite that underlies various kinds of soft tissue will be able to offer additional evidence on whether, for instance, large propulsive muscles really did lie along the projecting stalk of carroids, or whether the crystalline structure of the skeleton in that region is more consistent with other interpretations.

There may now be a break-through in the study of the echinoderm nervous system. Hitherto, workers have been hampered by the difficulty in recording either intra or extra-cellular potentials from individual nerves, because of their close packing and mostly small size. Now, however, it looks as though recording is possible, at least in those echinoderms which have recently been shown to possess giant fibres. An American worker, P. H. Brehm, has succeeded in recording extracellularly from a single nerve axon, using refined suction electrodes on the giant fibres in the radial nerve cord of a brittle-star. J. L. S. Cobb (Gatty Marine Labora-

David Nichols is Professor of Biological Sciences at the University of Exeter.

tory, St. Andrews) reported to the London meeting that he has repeated Brehm's technique, and has recorded the potential along over 70 cm of a single brittle-star nerve upon photic stimulation. The way may now be open for much further progress in the study of the neurological basis of observed echinoderm behaviour which has until now proved so difficult.

Research effort in echinoderm biology is increasing. An *Echinoderm Newsletter* produced by D. L. Pawson

and M. E. Downey (US National Museum, Smithsonian Institution, Washington) is mailed to over 700 workers, and the three International Conferences have generated a surprisingly large response. At the two meetings this year there was talk of establishing a learned society devoted entirely to echinoderm biology, and of seeking support for a journal. Maybe this reflects a growing awareness that many marine habitats are dominated by this group of macroinvertebrates. □

Recombination in semiconductors

from P. T. Landsberg

RECOMBINATION processes in semiconductors have become increasingly important since the invention of the transistor. In semiconductor devices switching and storage times are governed by the recombination lifetimes of excess carriers, as is the photo-voltage generated in solar cells, and in light-emitting diodes it is the ratio of radiative to total life times that plays a crucial role. Fundamental work in the field of recombination was the subject of a meeting on Recombination in Semiconductors which took place in Southampton at the end of August. Sir Neville Mott gave the opening address and his support and interest was widely appreciated by the participants.

Many of the semiconductor mechanisms—certainly radiative and Auger recombination—are of interest in plasma physics. This includes the cascading of a non-equilibrium electron down a ladder of states with the emission of a boson at each step. In plasmas and gaseous nebulae for example the boson is a photon and we then have a radiative cascade. Another recent development in this field is the hybrid process of a phonon cascade and multi-phonon process for the last step, when the electron reaches the ground state of a deep centre from its first excited state (N. F. Mott, Cambridge).

What other bosons are there? Should we not also expect in due course to be working on a plasmon-cascade, as narrow gap semiconductors become the subject of more accurate experiments? Although this process does not appear to have been considered before, electron-hole recombination can be greatly increased if a narrow energy gap can be tuned to the plasmon or optical phonon energy. Photoconductivity measurements on semimetallic $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ alloys reported by Dornhaus and Nimtz (Cologne) have

now confirmed this view. Of course for far infra-red devices it is desirable for good detectivities to find ways of lengthening life times rather than shortening them; coherent plasmon emission is, however, brought closer.

The analogy between semiconductors and plasmas is driven home by low temperature photoexcitation. The electron-hole pairs may then be so tightly packed that there is not enough space for exciton orbits of 100 Å or so, and one then has an electron-hole plasma or liquid. Just as there are droplets formed in the transition between water and water vapour at high humidity, so one has in this case the possibility of drops of electron-hole liquid in an exciton gas. The drops can be made to coalesce by the application of strain fields and so can reach radii from 50 μm to 7000 μm. In a dynamic equilibrium excitons condense on the drops and split up into electrons and holes so as to replenish the pairs lost by recombination within the drops. Studies of these effects were reported by Kelso and Furneaux (Univ. of Calif., Berkeley) who suggested the importance of a constant (i.e. independent of the pair density) term in the drop recombination rate. The experiments can be done for example by studying the decay of luminescence after laser cut-off. While Auger recombination dominates in unstressed drops in Ge, it may be that impurity recombination gives rise to the constant term and dominates in the stressed case. The radiative recombination from the droplets may be expected to be about 8 Mev wide by considering the separation between the quasi-Fermi levels.

Using appropriate reduced variables yields phase diagrams for electron-hole drops which are remarkably similar to those found many years ago for a number of gases. For lower excitation one

tends to have an exciton gas without drops, and no drops form above a critical temperature. Other highly interesting recombination effects in the e-h plasma include the possibility of populating the direct minimum in Ge by a band-band Auger effect (Klingenstein and Schweitzer, Stuttgart Univ.).

The weaker concentration dependence of the Auger effect in degenerate ($\sim np$) compared with non-degenerate ($\sim n^2p, np^2$) materials is relevant when setting up the steady state equations for droplets. A stronger dependence even in the degenerate material can again be obtained if k-conservation is neglected or because of higher order effects ($n^{7/3}p$) as has been shown by Haug (*Solid-State Commun.* **22**, 537; 1977).

When we come to bound excitons, it was found some years ago that radiative decay dominates for direct gaps. In an interesting report it was suggested that for small direct gaps the Auger recombination dominates over the radiative mechanism. As the gap is made smaller the Auger effect comes more easily and the radiative transition is less easy. This can be studied in $\text{Hg}_{1-x}\text{Cd}_x\text{Te}$ whose energy gap E_g can be changed by varying x . The two mechanisms are equally important for $E_g \sim 0.5$ eV in this case (Osborn *et al.*, Caltech, Pasadena). The temperature dependence of the Auger effect gave $\sigma_A \propto n_{ex}^{-8/3}$ instead of n_{ex}^{-2} , where n_{ex} is the extrinsic carrier concentration (Gerhardt, Berlin and Dornhaus & Nimtz, Cologne). The luminescent decay kinetics for excitons bound to isoelectronic traps in the GaP (the light-emitting diode material) was discussed by Sternheim and Cohen (Haifa).

Multiphonon processes are another field of current interest. The configuration coordinate diagram for ground and excited states of a centre show that (for broadened vibrational energies) one can have at one and the same energy a low-phonon excited state and a many-phonon ground state. The multiphonon transition can be visualised in this way. Indeed the energy given up in this type of recombination (and also in some other mechanisms) can pass to a defect and enable it to diffuse or dissociate (Kimerling, Bell Labs.). One application of this idea (Hutchinson, Birmingham) is that a dislocation emits vacancies into the surrounding lattice as the recombination energy is dissipated, thus increasing trapping defects and causing degradation in devices such as lasers. If this were a

P. T. Landsberg is Professor in the Faculty of Mathematical Studies at the University of Southampton.

key degradation process, one would try to use dislocation-free material in these semiconductor devices. In solar cells the lattice perfection is of importance (Kazmerski, Solar Energy Research Institute, Golden), as is recombination as a limit on efficiency (Klimpke and Landsberg, Southampton).

Just as it is desirable to design experiments which make the energetic Auger electron visible in some sense when the Auger effect is believed to be important, so also in phonon transitions it is useful to have as direct a way as possible to find evidence for the emitted phonons. This was recently shown to be possible by experiments on GaAs using a superconducting bolometer consisting of a granular Al film (Narayanamurti *et al.*, *Phys. Rev. Lett.*, **40**, 63; 1978). They identified phonon emission and explained the fraction of longitudinal and transverse phonons in terms of selection rules. This work has now revealed an anisotropy in phonon generation when observations are made along different crystallographic directions, using n-GaAs epitaxial layers and also p-n junctions. There is a pleasing correlation with light output of dislocated p-n junctions suggesting that this process is an important mode of non-radiative recombination.

It is known that in GaP grown by liquid phase epitaxy dislocations limit the lifetime and hence the radiative output of green light-emitting diodes. Dimitradis *et al.* (UMIST, Manchester) showed how the lifetime increases in GaP as one leaves the neighbourhood of a single dislocation line, and how it approaches the bulk dislocation-free value at the distance of one diffusion length.

The radiative transitions between Landau levels in n-InSb observed in 1972 have now been studied further to find that the lifetime of excess carriers in the first Landau level is inversely proportional to the concentration in this level (Müller & Gornick, Vienna and Bridges & Chang, Bell Labs). Short times of $\sim 10^{-10}$ s are found for concentrations of the order of 10^{13} cm $^{-3}$. A new but expected effect which was reported by Street *et al.* (Xerox, Palo Alto) is the magnetic field enhancement of luminescence in amorphous silicon. It is related to the anomalous photoconductivity and one wonders how general this effect is, since a magnetic field can cause an increase in lifetime by a factor of order 20 at 4 K in Hg $_{1-x}$ Cd $_x$ Te.

Finally, a new technique of recombination centre photocurrent analysis suitable for inhomogeneous distributions of recombination centres was proposed by Lang & Henry of Bell Laboratories. □

Has Atlantis disappeared again?

from D. H. Tarling

THE popular imagination has been captured by the idea that the destruction of Atlantis, as outlined by Plato from Egyptian sources, was in fact a record of the eruption of the Thera volcano in the Aegean some 3,500 years ago—which destroyed the Minoan civilisation not only on the volcano itself, but also on Crete and the surrounding islands. (S. Marinatos *Antiquity*, **13**, 425; 1939, J. C. Luce *The End of Atlantis* Thames & Hudson, 1969). At the same time, scientists concerned with the area who had previously promoted this image seem to be revising their views and are now proposing only tenuous links between the eruption and the decline of the Minoan thalocracy. The problem is that there seems to be a distinct interval between the two events of the order of 50 years. If such a gap really exists, it seems unlikely that the civilisation was ended either by tsunami destroying their fleets or by volcanic ash-fall destroying their crops. This interval is of critical interest to archaeologists and historians, but the succession of events during the largest volcanic eruption in history—at least four times as powerful as the 1883 Krakatoa eruption—is also of interest to a much wider audience. To discuss these matters of common interest archaeologists and Earth scientists gathered for the 2nd International Thera Congress, sponsored by Peter Nomikos, and held aboard a ship cruising the relevant areas of the Aegean.

The geophysical-geochemical background to the Thera volcanic activity was, naturally, based on plate tectonic models in which an East Mediterranean plate is descending to some 110–140 km beneath the Aegean, from which volcanic magmas are currently being derived (H. Berckhemer, Frankfurt; D. Kiskyras, Athens; B. C. Papazachos & P. D. Comninakis, Thessalonika). Geochemical evidence of major, trace and rare earth distribution were in remarkably good agreement for a model in which water released from the descending plate caused partial melting in the mantle wedge overlying it (I. A. Nicholls, Monash; H. Puchelt, Karlsruhe; R. S. Taylor, Canberra) and the magmas are therefore unrelated to descending slab, except indirectly, and are also virtually free of contamination from the thin, overlying Aegean crust. The Aegean, in fact, seems to have a thin crust that is currently in tension (N. C. Fleming, Godalming)—a surprising observation

when it is considered that most of the surrounding areas are under strong compressive stress. This situation is probably related to convective circulation beneath this marginal basin, although it is important to distinguish major differences between this area and the Pacific margin. Around the Western Pacific, earthquake activity proceeds to much greater depths than in the Aegean and oceanic crust is being subducted, whereas the Eastern Mediterranean crust is generally considered to be exceptionally thick oceanic or thin continental crust.

However, as earthquake activity in the Aegean has only been recorded in detail for something like the past 50 years and only with adequate precision for the past 10 years or so, comparison with the Pacific margin is still needed to evaluate possible relationships between earthquake and volcanic activity. C. Blot (Solles-Pont) made analogies with Guatemala, in particular, to predict that major earthquakes about 100 km beneath Thera would be followed some 1½ to 2 years later by either an eruption or major shallow earthquake on Thera and that this would be followed, some 3 years later, by strong shallow earthquakes in the area of Crete. Unfortunately the precise relationship between earthquake and volcanic activity is still to be firmly established, and many earthquakes seem to be unrelated, in any direct fashion, to magma migrations. It is difficult therefore to apply such models to explain the apparent time-gap between the archaeological evidence for earthquake activity and subsequent volcanic activity and then further possible earthquake activity.

Surprising unanimity was also expressed by volcanologists attending the Congress. There was, for example, agreement that the volcanic deposits were related to only one cycle of volcanic activity and that this activity, by analogy with Krakatoa 1883, probably took place during a single day (C. J. & D. Vitaliano, Indiana; H. Pichler, Tübingen; W. L. Friedrich, Aarhus, R. W. Decker, Dartmouth). This contrasts with previous interpretations of some ash-falls as being related to up to three distinct eruptions, with possible intervals of a decade or so between each fall. This unanimity reflects increasing understanding of volcanic processes and geochemical evidence for the uniformly increasing basicity of the tuffs as the pumice was generated (C. J. Vitaliano *et al.*, Indiana). It is now clear that the earth-

D. H. Tarling is in the Department of Geophysics and Planetary Physics, University of Newcastle-upon-Tyne.

quake that destroyed the Minoan city of Akrotiri, on Thera, occurred long enough before the eruption—to allow people to return and attempt some initial clearance (C. Doumas, Thera). The eruption itself clearly started with an ash-fall of ~1–2 m thick over the city and was preceded by a very fine pumice fall, only some 1–2 cm thick, which may have been sufficient warning for those clearing the site. The main pumice, however, seems to have been in the form of a base surge, followed by a chaotic ash-flow stage during which large volcanic bombs continued to be spouted out of the volcano. There were clearly no distinct *nuée ardente* deposits, although some pumice debris on wall frescoes has been used to determine the direction of flow of these glowing dust clouds (P. Hédervari, Budapest). One of the most puzzling observations was that preliminary palaeomagnetic data indicated that the walls of the Minoan city had not even been warmed by the volcanic debris and that both the ash-fall, base-surge and ash-flow deposits seemed to have been emplaced very close to room temperature (D. H. Tarling, New-castle), thereby indicating mud-flow origin (A. Bond & R. S. J. Sparks, *J. Geol. Soc.*, **132**, 1: 1976) at ambient temperatures. Whatever the origin, there was clear agreement that these deposits were all accumulated in a very short time so that the interval between the Thera eruption and the end of the Cretan thalocracy could not be interpreted in terms of a succession of eruptions spread over, for example, 50 years. There was also surprising agreement on the improbability of the pumice ash, that undoubtedly fell on eastern Crete (F. W. McCoy, Columbia), having any great effect on the harvest for that or subsequent years unless the pumice also included poisonous gases, such as fluorine (D. Vitaliano, Indiana). It was even suggested that the thin ash-fall, at most 5 cm thick, could have been beneficial.

The effects of tsunami (I. Yokoyama, Hokkaido), associated with either the earthquake or volcanic eruptions, received surprisingly little direct attention. In general, most earth scientists were mainly concerned with establishing that any tsunami would not have affected ships at sea and any effects would be restricted to the damage of ships at anchor and harbour installations. There is little evidence for harbours along northern Crete at that time (N. C. Fleming, Godalming)—an observation which received little comment yet must have important implications for the idea of a thalocracy governed from Crete. The only solution seems to be that the catastrophic series of events had such a psychological im-

pact that any religious-based administrative system would have collapsed. Nonetheless, such a disintegration would still be expected in late Minoan IA times and not up to 50 years later. The ^{14}C dating of both short-lived materials (grain, shrubs, burnt bone for example) and long-lived materials has raised more problems than it has solved (P. Betancourt, M. Biddle & E. Ralph, Philadelphia). Unlike most other sites, both types of material show an extraordinary range in values, with 70% of the ages for both types of material more than one standard deviation older than the expected 1500–1400 BC date—an age which is known from the good correlations between the precise Egyptian chronology and Minoan pottery styles on Crete. Although the Congress was only presented with the carbon dates, it seems that the only sensible interpretation is that the region of Akrotiri was completely abnormal for well before the earthquake which was to destroy it. It seems unlikely that the ^{14}C dates have been affected by later contamination as most of the materials were well sealed with the archaeological deposits, so the most likely, but still imponderable, explanation is that the vegetation in the area was accumulating varying degrees of old carbon in its structure whilst growing. The processes by which this occurred are unclear, as any volcanic gas emanations would rapidly mix with the atmosphere and clearly much more detailed study is required to establish how such a situation may arise as it is clear that the normal assumptions on which ^{14}C is based do not seem to be valid here and must raise doubts as to their validity in other situations, until the cause of the internal scatter in the Akrotiri materials can be satisfactorily explained.

The archaeological basis for a difference in age between the Thera eruption and the Minoan decline has changed little. In general, most archaeological and historic studies confirm that there was a real time-gap between the Late Minoan IA pottery motifs found in Thera and those extant in the Late Minoan IB period in Crete at the time of the takeover by the Mycenaeans (S. Hood, Oxford; A. Furumark, Uppsala). The evidence suggests that the takeover was not a deliberate invasion but that a Mycenaean exploratory fleet came across a Minoan Empire that was in complete disarray for unclear reasons.

To some extent, therefore, Earth scientists have provided a somewhat more uniform picture of the sequence of events during the Thera earthquake and eruption, but such models are still likely to be drastically modified if archaeological evidence can be ob-

tained for a revision of the relationship between several earthquake events during the period 1500–1400 BC and the volcanic eruption. It will be surprising, however, if such a major series of tectonic events should not be directly related to the otherwise puzzling, rapid decline of the Minoan civilisation at a similar time. □

A hundred years ago

AMONG the resolutions passed by the International Congress on Weights, Measures, and Coins, at Paris, was the following:—The Congress learns with pleasure the progress of the metric system; it deplores that England, Russia, and the United States have not yet entered into the same path; and it is of opinion that the Governments of those countries should be solicited to give effect as early as possible to an act of progress so eminently useful to science, commerce, and international relations." The British and American members had a separate meeting, and resolved to petition their respective Governments to appoint a mixed commission to consider adoption of the metric system by both countries, and to make all necessary recommendations for the proper legislation to secure the desired end.

I AM able to confirm the accounts given by Mr. Simson in your last number as to the probability of the hearing of insects. When travelling on the River Magdalena, New Granada, in 1861, the mode of which is by a long boat, arched over with bamboo, on which the sailors (bogás) passing from one extremity to the other, propel it with long poles, hugging the river bank, accompanied with wild cries and execrations, I observed on several occasions that these cries suddenly ceased, a dead silence following, and on inquiring the cause they pointed to nests high up in the trees, whispering the word *vispa* (wasp). As the bogás pursue their avocations in a state of semi-nudity, they have the greatest dread of these insects, fearing to speak aloud, as their only alternative if attacked by them is to plunge into the stream, where alligators abound. The wasp is long, slender, and black in colour.

review article

The tau heavy lepton—a recently discovered elementary particle

Martin L. Perl*

This review recounts the history of the discovery of the tau heavy lepton. Evidence for the tau being a lepton is summarised and the known properties of the tau are discussed.

THERE is now very substantial evidence for the existence of a new elementary particle called the tau (τ). (The name τ is taken from the first letter of the Greek word $\tau\alpha\upsilon\rho\nu$. It signifies that the τ is the third charged lepton to be found, the first two being the electron and the muon.) Elementary particles are the simplest forms of matter and through studying them we hope to understand the fundamental nature of matter. As I will show in this article, the properties of the τ are analogous to the properties of the electron (e) and muon (μ). Therefore, the τ has been classified as a member of the lepton particle family (Table 1) even though it is much heavier than the e or μ , having a mass of almost $1,800\text{ MeV}/c^2$. The discovery of this new lepton has particular significance in the world of elementary particles because the lepton family has so few members, and because the τ is so relatively massive. One purpose of this article is to discuss that significance; the other purposes are to outline the evidence for the existence of the τ and to describe its properties as far as we know them.

The first evidence^{1,2} for the existence of τ leptons was found at the SPEAR electron-positron colliding beams facility of the Stanford Linear Accelerator Center (SLAC). The τ 's were produced through the electron-positron annihilation reaction

$$e^+ + e^- \rightarrow \tau^+ + \tau^- \tag{1}$$

a simple reaction whose theory is well understood. All subsequent studies of the τ at SPEAR and at DORIS, the electron-positron colliding beams facility at the Deutsches Elektronen-Synchrotron (DESY), have used reaction (1). (See refs 3–6 for reviews on τ .) Therefore, in this article, I shall limit my discussion of the production of τ 's or other heavy leptons to this reaction.

The unique position of the leptons in elementary particle physics is illustrated by Table 2 which summarises the differences between the lepton and hadron families. The hadrons are composite particles made up of constituents we call quarks; the hadrons interact through the strong interactions which at high energies can lead to very complicated reactions in which many hadrons are produced; and the hadrons occur in more than 100 different types. (See refs 7, 8 for reviews on quarks.) In stark contrast: the leptons are simple, nondivisible particles; they do not partake in the strong interactions; even at high energies the reactions in which the leptons directly play a part only produce a few particles (that is, the lepton vertex in the Feynman diagram of the reaction produces only a few particles); and as I have already noted, there are only a few types of leptons. Therefore, the leptons, in contrast to the hadrons, are truly

elementary particles; and in studying the leptons we are studying directly the simplest forms of matter which we have yet discovered. The quarks may also be truly elementary particles; however, we do not know if they can be isolated in a free state; and at present, we can only study them very indirectly. Until the discovery of the τ one might have thought that the simplicity and truly elementary nature of the leptons were connected with their small mass. The e , the μ and their neutrinos have less mass than the lightest hadron—the π^0 with a mass of $135\text{ MeV}/c^2$. (The name lepton means 'light one' in Greek.) However, the τ is heavier than many hadrons and its existence once and for all separates the concept of a particle's elementarity from the size of a particle's mass. Indeed, we emphasise this by referring to the τ by the oxymoron 'heavy lepton'.

Lepton conservation and the sequential heavy lepton model

Our search for heavy leptons which led to the discovery of the τ was based on the sequential heavy lepton model⁹. We could have used other models^{10,11} in our search; however, the elegance, symmetry and simplicity of the sequential model appealed to us. To our surprise, the properties of the τ are consistent with its being a sequential heavy lepton. The sequential model is based on extending the concept of lepton conservation to heavy leptons. Lepton conservation is the explanation of why reactions such as

$$\mu^- \not\rightarrow e^- + \gamma \tag{2}$$

$$\text{or} \quad e^+ + e^- \not\rightarrow \mu^+ + e^- \tag{3}$$

do not occur. Taking reaction (2) as the simplest example; lepton conservation asserts: (1) that the e and the μ each possess a unique property not possessed by the other particle, (2) that those properties cannot be destroyed in a reaction, and hence (3) that a μ cannot change into an e . This concept is codified in a

Table 1 The lepton particle family

Name	Electron	Muon	Tau
Charged lepton	$e^\pm$	$\mu^\pm$	$\tau^\pm$
Charged lepton mass (MeV/c^2)	0.51	105.7	$1,782^{+2}_{-7}$
Charged lepton lifetime (s)	Stable	2.20×10^{-6}	$<3.5 \times 10^{-12}$
Associated neutrino	$\nu_e, \bar{\nu}_e$	$\nu_\mu, \bar{\nu}_\mu$	$\nu_\tau, \bar{\nu}_\tau$
Associated neutrino mass	$<60\text{ eV}/c^2$ (may be 0)	$<0.57\text{ MeV}/c^2$ (may be 0)	$<250\text{ MeV}/c^2$ (may be 0)

* Stanford Linear Accelerator Center, Stanford University, Stanford, California 94305.

Table 2 Comparison of leptons and hadrons		
Family	Lepton	Hadron
Structure	Simple particle, no structure or constituents found by experiments	Composite particle constituents are quarks
Interacts through strong interactions	No	Yes
Interacts through electromagnetic interaction	Only if charged	Yes, in all cases
Interacts through weak interactions	Yes	Yes
Interacts through gravitational interaction	Yes	Yes
No. of types found so far	6 if ν_τ is unique	>100

more mathematical form in Table 3 where the e^- and its associated neutrino ν_e are assigned the 'electron lepton number' $\eta_e = +1$, and so on. Lepton conservation then states that in any reaction the separate sums of η_e and η_μ on one side of a reaction must equal their respective sums on the other side. For example: reaction (2) does not occur because on the left side $\eta_e = 0$ and $\eta_\mu = 0$ while on the right side $\eta_e = +1$ and $\eta_\mu = -1$. In contrast to reaction (3), the reaction

$$e^+ + e^- = \mu^+ + \mu^- \tag{4}$$

can occur because η_e and η_μ are zero on both sides. Indeed, reaction (4) is a well known and well studied reaction.

An important consequence of lepton conservation is that decay of the μ to an e occurs not through the simple reaction in equation (1) but through the complicated reactions

$$\mu^- \rightarrow \nu_\mu + e^- + \bar{\nu}_e \tag{5a}$$

$$\mu^+ \rightarrow \bar{\nu}_\mu + e^+ + \nu_e \tag{5b}$$

It is important to note that the decays in equation (5) take place through the weak interactions. The μ cannot decay through the strong interactions because it is not affected by the strong

Fig. 1 Theoretical prediction for the lifetime of a sequential heavy lepton with V-A coupling and conventional weak interactions.

interactions; and the μ cannot decay through the electromagnetic interaction because the electromagnetic decay channel, reaction (2), violates lepton conservation. Lepton conservation also dictates how hadrons can decay to leptons. For example, the decays

$$\pi^- \rightarrow \mu^- + \bar{\nu}_\mu \tag{6a}$$

$$\pi^- \rightarrow e^- + \bar{\nu}_e \tag{6b}$$

can and do occur.

Before returning to the sequential heavy lepton model, I should remark that we have no deep understanding of lepton conservation; that is, we do not know how or in what way a μ differs from an e . As an experimenter, I regard lepton conservation simply as an empirical rule whose underlying significance we may one day understand through further experimentation with leptons.

The sequential heavy lepton model⁹ simply assumes that there is a mass sequence of charged leptons and associated neutrinos:

Charged lepton	Associated neutrino
$e^\pm$	$\nu_e, \bar{\nu}_e$
$\mu^\pm$	$\nu_\mu, \bar{\nu}_\mu$
$\tau^\pm$	$\nu_\tau, \bar{\nu}_\tau$
$\vdots$	$\vdots$

It further assumes that each type of lepton has a unique lepton number which is separately conserved in every reaction. Using this idea and assuming that the mass of the τ (m_τ) is sufficiently large, the τ should decay through the reactions

$$\tau^- \rightarrow \nu_\tau + e^- + \bar{\nu}_e \tag{7a}$$

$$\tau^- \rightarrow \nu_\tau + \mu^- + \bar{\nu}_\mu \tag{7b}$$

Table 3 Values of lepton numbers for various particles			
Particle	Electron lepton number, η_e	Muon lepton number, η_μ	Tau lepton number, η_τ
e^-, ν_e	+1	0	0
$e^+, \bar{\nu}_e$	-1	0	0
μ^-, ν_μ	0	+1	0
$\mu^+, \bar{\nu}_\mu$	0	-1	0
τ^-, ν_τ	0	0	+1
$\tau^+, \bar{\nu}_\tau$	0	0	-1
All hadrons	0	0	0

This table assumes the τ is a sequential heavy lepton with its own lepton number η_τ .

These decay channels are analogous to the μ decay channel in reaction (5a): they take place through the weak interactions and they obey lepton conservation. (In the remainder of this article, I shall only write decay reactions for the τ^- , as the τ^+ decay can simply be obtained by reversing the signs of all the charged particles and interchanging neutrinos and antineutrinos.) An exciting consequence of this model is that a sufficiently massive heavy lepton ought to decay to hadrons—just the reverse of reaction (6) in which a hadron decays to leptons. For example, decays such as

$$\tau^- \rightarrow \nu_\tau + \pi^-$$

$$\tau^- \rightarrow \nu_\tau + \pi^- + \pi^0 \tag{8}$$

and

$$\tau^- \rightarrow \nu_\tau + \pi^- + \pi^+ + \pi^-$$

should occur. These decays would occur through the weak interactions.

The lifetime of a sequential heavy lepton decreases as its mass increases because as the mass of a particle increases it becomes more unstable, and because more decay channels, such as those in equation (8), are available. If one assumes that the sequential

Fig. 2 A cross-sectional view of the SLAC-LBL magnetic detector. The e^- and e^+ beams move along an axis (perpendicular to the paper) inside the beam pipe. The concrete absorber was an addition to the detector used to detect μ -hadron events from τ decays.

heavy lepton has the same type and strength of weak interactions as the μ and e , then its lifetime can be calculated¹¹⁻¹³ (Fig. 1). When we began our search, we already knew that there were no sequential heavy leptons with masses less than 1,000 MeV/ c^2 . This lower limit had been set by experiments^{14,15} carried out at the ADONE electron-positron colliding beams facility at Frascati, Italy. Therefore, as shown in Fig. 1, the heavy leptons we were seeking would have lifetimes so short that they would decay before reaching our detection apparatus; hence they would have to be detected through their decay products. How this was done is the subject of the next section.

Evidence for the τ particle

$e\mu$ Events. We used the SLAC-LBL magnetic detector at SPEAR for our search (Fig. 2). This detector gathered information on electron-positron annihilation events in which at least two charged particles appeared in the apparatus. We knew that the vast majority of these events had nothing to do with heavy leptons. However, we searched through the events for the events in which only two particles were observed: one an electron and the other a muon, the two particles having opposite electric charge.

These $e\mu$ events could come from the reaction and decay sequence

as neutrinos pass unobserved through the detector (Fig. 3). This is a strong signature for heavy lepton production because lepton conservation forbids the production of only an e and μ in the final state; and there are very few reactions in which only an e , a μ and neutrinos are produced. Furthermore, reaction (9) is distinctive because there is on the average a large amount of energy carried off by the neutrinos and hence unobserved.

In the winter of 1974-75 we began to find^{1,2} $e\mu$ events when the total energy, E_{total} , of the e^+ and e^- beams at SPEAR was above $\sim 4,000$ MeV. Because in the reaction $e^+ + e^- \rightarrow \tau^+ + \tau^-$ two τ 's must be produced, this meant that the mass of the τ had to be less than 2,000 MeV/ c^2 . We were also able to place a

lower limit of about 1,600 MeV/ c^2 on m_τ by studying the momentum distribution of the e and μ in reaction (9). By the summer of 1976, we were able to show¹⁶ that all the properties of the 105 $e\mu$ events we had by then accumulated were consistent with these events being from heavy lepton production.

Figure 4 illustrates one of the consistency tests. The momentum spectrum of the e or the μ produced in reaction (9) through the three-body decays of the τ 's, reaction (7), is described by the solid curve in Fig. 4a. If the τ decayed differently, say by a two-body decay $\tau \rightarrow e + \nu$ or $\tau \rightarrow \mu + \nu$, then the dashed curve would result. Figure 4b shows our measurement¹⁷ of the e and μ spectrum. We could not detect the slow e 's or μ 's required for the low momentum, ascending part of the solid curve in Fig. 4a; however, our measurement was clearly consistent with the high momentum part of that curve. And our measurement is clearly inconsistent with the two-body decay of the τ . A later but more complete measurement of the e momentum spectrum from $e\mu$ events is shown in Fig. 4c. This was obtained by Burmeister *et al.*¹⁸ using the PLUTO detector at DESY.

Of course, the existence of a heavy lepton is not demonstrated simply by showing that $e\mu$ events have properties consistent with those of a lepton. One must also show that there is no other source of the $e\mu$ events. One alternative source which was often suggested was the production and decay of a pair of charmed mesons.

If the final hadrons were not detected, then reaction (10) might resemble reaction (9). My colleague, Gary J. Feldman, was able to show¹⁶ that the majority of our $e\mu$ events did not have undetected hadrons accompanying them.

A very clear proof that $e\mu$ events did have accompanying hadrons, detected or not detected, was produced by the group using the PLUTO detector. They showed¹⁸ that in a data sample which contained 23 $e\mu$ events there were no events of the type $e\mu + \text{hadrons}$.

There was another important result of demonstrating that $e\mu$ events did not have accompanying hadrons. It showed that the reaction

and not the reaction

was the source of $e\mu$ events. We do not expect reaction (12) to

Fig. 3 A schematic diagram of how $e\mu$ events are produced. The τ 's are produced at point (a) where the e^+ and e^- beams collide. They decay close to point (a) at points (b) and (c) while still inside the beam pipe (see Fig. 2). Therefore only the decay products reach the detector. However, the neutrinos, indicated by dashed lines, cannot be observed in the detector, only the e and μ are observed.

be a source of heavy leptons, and the absence of reaction (12) was an additional proof that the τ was a lepton.

μ -Hadron events. If we accepted the $e\mu$ events as coming from the production and decay of a pair of τ heavy leptons, then the sequential heavy lepton model and the mass of the τ being greater than $1,600 \text{ MeV}/c^2$ would require the existence of other rather strange types of events. Thus the reaction and decay sequence

should occur, where the $\tau^- \rightarrow \text{hadrons} + \nu_\tau$ decay is one of the types in equation (8). These events are called μ -hadron events. We were particularly interested in the μ -one-charged-hadron events in which there was just one charged hadron, because such events were unlikely to come from other sources such as charmed meson production. In 1976 a small sample of μ -one-charged-hadron events was found at SPEAR by Cavilla-Sforza *et al.*¹⁶. Later in 1976, after having added an improved muon detection system to the SLAC-LBL magnetic detector (Fig. 2), we were able to report the finding of a large sample of μ -one-charged-hadron events²¹. And physicists using the PLUTO detector at DORIS also found²² such events. As with the $e\mu$ events, all the properties of these μ -hadron events were consistent with the τ being a heavy lepton.

Fig. 4 *a*, The solid curve is the theoretical momentum spectrum of the e or μ coming from the three-body decay $\tau \rightarrow e(\text{or } \mu) + \nu + \bar{\nu}$ of a moving τ . The dashed line is the theoretical momentum spectrum of the e or μ from a two-body decay $\tau \rightarrow e(\text{or } \mu) + \nu$. The comparison of the three-body decay curve with the data is made in (b) for the SLAC-LBL magnetic detector results (ref. 17) and in (c) for the PLUTO detector results (ref. 18). The curves in (b) and (c) are corrected for apparatus acceptance and the spread in E_{total} ; hence they differ slightly from the curve in (a). In (b) the apparatus could not identify e 's or μ 's in the low momentum region marked.

e -Hadron events. The symmetry of the sequential heavy lepton model with respect to τ decays to μ 's and e 's, equation (7), requires that e -hadron events as well as μ -hadron events exist. To find such events it was necessary to have a detector which could precisely separate electrons from hadrons. The DASP detector²³ at DORIS was the first e^+e^- colliding beams detector to have that ability. As shown in Fig. 5, this separation is obtained by using Cerenkov counters. In 1977 the group using DASP was able to find²⁴ the e -one-charged-hadron events expected from the reaction

and more recently physicists using a very large solid angle Cerenkov detector at SPEAR, called DELCO²⁵, have found a very large sample of e -one-charged-hadron events. With the finding of these events, and the determination that their properties were consistent with heavy leptons as their source, the discovery stage of the work on the τ lepton ended. We are now in the stage of detailed study of the τ and measurement of its properties. This is the subject of the next section.

Properties of the τ

Mass of the τ . The most recent measurement of the mass of the τ carried out by the DELCO collaboration²⁶ yields

$$m_\tau = 1,782_{-7}^{+2} \text{ MeV}/c^2 \quad (15)$$

This value was obtained by measuring the cross section, σ_{eh} , for the production of e -one-charged-hadron events as a function of the energy E_{total} . If the τ is a lepton, σ_{eh} should obey the equation

$$\sigma_{eh} = P_{eh} \frac{4\pi\alpha^2}{3E_{\text{total}}^2} \left[\frac{\beta(3-\beta^2)}{2} \right] \quad (16a)$$

Here P_{eh} is the probability that a τ pair decays to an e -one-charged-hadron event; α is the fine structure constant; and $\beta = v/c$ where v is the velocity of the τ and c is the velocity of light. It is conventional in e^+e^- annihilation physics to remove the E_{total}^2 term in equation (16a) by defining the ratio

$$R_{eh} = \frac{\sigma_{eh}}{\sigma_{e^+e^- \rightarrow \mu^+\mu^-}} = P_{eh} \left[\frac{\beta(3-\beta^2)}{2} \right] \quad (16b)$$

Here

$$\sigma_{e^+e^- \rightarrow \mu^+\mu^-} = \frac{4\pi\alpha^2}{3E_{\text{total}}^2} \quad (16c)$$

is the cross section for reaction (4). In equation (16b) as E_{total} increases, β approaches 1 and R_{eh} approaches a constant, namely P_{eh} . Figure 6a shows²⁶ R_{eh} . The E_{total} where R_{eh} begins to rise above zero is called the threshold energy, E_{thresh} , and m_τ is given by $E_{\text{thresh}}/2$. The behaviour of R_{eh} in Fig. 6a and of $R_{e\mu}$ in Fig. 6b are consistent with equation (16b) and hence consistent with the τ being a lepton. ($R_{e\mu} = \sigma_{e\mu}/\sigma_{e^+e^- \rightarrow \mu^+\mu^-}$ where $\sigma_{e\mu}$ is the cross section for producing $e\mu$ events.) An older value of m_τ obtained by the DASP collaboration²⁴ is

$$m_\tau = 1,807 \pm 20 \text{ MeV}/c^2$$

Mass of the ν_τ . The DELCO collaboration²⁵ gives an upper limit of

$$m_{\nu_\tau} \leq 250 \text{ MeV}/c^2$$

with 90% confidence; m_{ν_τ} could be zero. The masses of the e and μ neutrinos may also be zero (Table 1).

Lifetime of the τ . The PLUTO collaboration finds

$$\tau \text{ lifetime} \leq 3.5 \times 10^{-12} \text{ s}$$

with 95% confidence. The theoretical prediction for this lifetime is $2.5 \times 10^{-13} \text{ s}$.

The coupling of the τ to the ν_τ . The data favour V-A coupling of the τ to the ν_τ . This, of course, is the coupling predicted by conventional weak interaction theory.

Spin of the τ . Measurement of the behaviour of the cross section for $e^+ + e^- \rightarrow \tau^+ + \tau^-$ as a function of E_{total} strongly favours^{3,4,25} the spin of the τ being 1/2. This has been discussed in detail by Tsai²⁷. The spins of the e , μ and their neutrinos are also 1/2, hence the τ on the basis of its spin is a conventional lepton, if we can call a heavy lepton conventional.

Decay modes of the τ . Table 4 lists the observed decay modes of the τ and compares the measured fractional decay rates with the theoretical predictions. These predictions are recent calculations of Tsai¹³ based on conventional weak interaction theory and V-A coupling. In all the measured modes the data and the theory agree; this is another reason for believing that the τ is a lepton.

Lepton type of the τ . All measurements on the τ are consistent with its being a sequential heavy lepton with a unique and separately conserved lepton number. It has been shown^{28,29} that the τ^- does not have the lepton number of the μ^+ or μ^- , nor does it have the lepton number of the e^+ (ref. 30). However, it is possible the τ^- could have the lepton number of the e^- —we have not been able to rule out this possibility experimentally. But this leads to an ugly theory in which the decay

which has not been observed, must be prohibited or suppressed by means other than lepton conservation. My prejudice is that the sequential heavy lepton model, which has guided us so well, will in the end be the correct choice.

Future work on the τ . Studies of the properties of the τ are continuing at SPEAR and DORIS and will also be undertaken at the three new, higher energy, electron-positron colliding beams facilities. These new facilities are PEP at SLAC and PETRA at DESY each with a maximum E_{total} of about 36 GeV, and CESR at Cornell with a maximum E_{total} of about 18 GeV. One direction of these new studies will be to learn more about the decay mode of τ . For example, do decay modes such as $\tau^- \rightarrow K^- + \nu_\tau$ exist at the predicted 1% decay rate? Or does the decay mode $\tau^- \rightarrow e^- + e^+ + e^-$, forbidden by the sequential lepton model, but predicted by other models, exist?

At the higher energy e^+e^- facilities, we can test in more detail our present conclusion that the τ is a lepton. We have come to this conclusion by using Occam's razor and asserting that a charged particle is either a lepton or a hadron. But suppose the τ is some very strange new kind of particle which is 90% leptonic and 10% hadronic in nature. We might expect that the 10%

Table 4 Comparison of predicted and measured fractional decay rates for the τ

Decay mode	Predicted fractional decay rates	Measured fractional decay rates	Groups making measurements
$\tau^- \rightarrow \nu_\tau + e^- + \bar{\nu}_e$ or $\tau^- \rightarrow \nu_\tau + \mu^- + \bar{\nu}_\mu$	16%	16 to 19%	DASP DELCO SLAC-LBL
$\tau^- \rightarrow \nu_\tau + \tau^-$	10%	6 to 11%	DELCO SLAC-LBL PLUTO
$\tau^- \rightarrow \nu_\tau + \rho^-$	23%	24 ± 9%	DASP
$\tau^- \rightarrow \nu_\tau + \geq 3$ charged hadrons	28%	16 to 32%	DELCO MPP PLUTO SLAC-LBL

Where several measurements have been made, the range of values is given. Numbers are rounded off to the nearest per cent. See refs 3, 4 and 25 for details and references.

Fig. 5 A section of the DASP detector showing the Cerenkov counter. Redrawn from ref. 23.

hadronic component would show itself at very high energies through the reaction

If, however, the reaction

continues to behave at very high energies as it does at the energies now available, then we shall have additional proof that the τ is a pure lepton.

Leptons and quarks

I conclude this article with two remarks on the possible impact of the discovery of the τ on elementary particle physics. First, we have never understood how to calculate the masses of elementary particles. For example, we do not have the least idea why the mass of the electrons is $0.51 \text{ MeV}/c^2$. Perhaps the discovery of the τ will provide a clue as to how to calculate masses because now for the first time we know the masses of three truly elementary particles: the e , μ and τ . (The neutrinos seem to have zero mass which is not much of a help to calculations.)

Second, as noted above, it has become customary to regard the hadrons as composite particles made up of more elementary particles—the quarks. One then regards the quarks and leptons as two different but similar families of truly elementary particles. Furthermore, in some theories the numbers of leptons are equal to the numbers of quarks. For example, before the discovery of the τ there seemed to be four leptons and four quarks:

Leptons: e, μ, ν_e, ν_μ ; Quarks: u, d, s, c

The discovery of the τ upset this equality. However, it may be restored as follows. If the τ is a sequential heavy lepton, its neutrino, ν_τ , is unique and constitutes a sixth lepton. The discovery of the upsilon particle indicates the existence of a fifth quark called b . If we are then willing to believe that a sixth quark, usually called t , also exists, there is again lepton-quark numerical equality:

Leptons: $e, \mu, \tau, \nu_e, \nu_\mu, \nu_\tau$; Quarks: u, d, s, c, b, t (17)

Many elementary particle physicists would like to see this closed system of twelve elementary particles, with the addition of the intermediate bosons $W^\pm, Z^0$, constitute the fundamental nature of matter. (I am simplifying here. Most theories also require other particles, such as the gluons, which are supposed to carry the forces between the quarks.) After all, such closed systems of elementary constituents have played crucial parts in physics up to now. We explain the long series of atoms as being made of different combinations of electrons around a nucleus; and we

Fig. 6 Behaviour of (a) $R_{\pi^0}^2 = \sigma_{\pi^0}/\sigma_{\pi^0+\pi^0 \rightarrow \mu^+\mu^-}$ from DELCO²⁶; and of (b) $R_{\pi^0}^2 = \sigma_{\pi^0}/\sigma_{\pi^0+\pi^0 \rightarrow \mu^+\mu^-}$ from the SLAC-LBL magnetic detector collaboration^{3,4}.

explain the hundreds of different kinds of nuclei by different combinations of neutrons and protons. If the system of truly elementary particles is closed as in equation (17), then we will also be able to explain the hundred or more kinds of hadrons as various combinations of quarks. And the lepton will remain a relatively simple and sparse family with the τ being the only heavy lepton.

There is an alternative possibility which intrigues me. Perhaps the τ is the beginning of a long, or even infinite, series of heavy leptons; and perhaps these leptons are truly elementary, as the e , μ and τ seem to be. Then the elementary particle physicist will

face a situation unique in physics: a large number of related entities whose properties cannot be explained in terms of a much smaller number of more fundamental entities. Then our present ways of theorising about elementary particles will not work and we will need some radically new ideas. Of course, this is speculation; and for experimenters, there is an obvious task which precedes this speculation. We must find out whether the τ is the first and last of the heavy leptons, or whether it is only the beginning of a sequence of heavy leptons.

Recurrent activity in galactic nuclei

M. E. Bailey

Department of Astronomy, University of Edinburgh, Edinburgh, UK

S. V. M. Clube

Royal Observatory Edinburgh, Blackford Hill, Edinburgh, UK

Arguments are presented to support the hypothesis that massive galaxies periodically undergo phases of nuclear activity during their evolution at intervals 10^8 – 10^9 yr. The importance of recurrence to theories of active nuclei is emphasised. In particular, the evidence does not favour the production of massive black holes in galactic nuclei.

THEORETICAL investigations into the problems raised by activity in galactic nuclei have, until recently, concentrated almost exclusively on the hypothesis that nuclear activity (as evidenced by the quasar, Seyfert or radio-galaxy phenomena) is

an essentially singular occurrence in the lifetime of a massive galaxy. The possibility that nuclear activity might be a recurrent phenomenon has been considered, but as yet no compelling reasons for preferring one or other hypothesis have been presented. In this article we assess the observational evidence bearing on this question and outline a theory to account for recurrence. Implications of the establishment of recurrence as a fundamental phenomenon affecting the evolution of galaxies are discussed.

Observational evidence for recurrent activity

As there is no general agreement as to either the nature or the evolution of a galactic nucleus, it is still not possible to determine

unambiguously how any one property of a galaxy relates to nuclear activity, recurrent or otherwise. Nevertheless, a past period of activity might be considered to manifest itself in at least one or more of the following ways in normal galaxies: (1) by the existence of a massive nonstellar remnant²; (2) by a burst of star formation in the nuclear region³; (3) by noncircular motions in the nuclear region⁴; (4) by characteristic radio spectra and structures^{5,6}; and (5) by jets⁷ or unusual arms emerging from nuclei^{8,9}. In some instances, the evidence can testify only to at least one period of activity (for example, (1)), or to recent activity (for example, (5)); but in other cases it is possible in principle to compare the observable timescale of a given signature (τ_0) with the cumulative duration (τ) of the phenomenon inferred from its frequency amongst particular galaxy types. The ratio $R = \tau/\tau_0$ is then a measure of the number of events during a galactic lifetime.

If a burst of massive star formation is triggered by a period of nuclear activity—for example, either by immediate condensation of expelled gas or by passage of shocks—the timescale τ_0 may be estimated from the expected lifetimes of a nuclear H II region or the time required for an initial burst to affect the whole nuclear region, to be $\leq 5 \times 10^7$ yr. The central regions of $\sim 10\%$ of spirals show narrow nuclear emission lines associated with a recent burst of star formation^{10–12}, so in this case $\tau \sim 10^9$ yr, giving $R \geq 20$.

Noncircular motions might in principle have a number of separate causes (such as tidal interaction, or action of a bar), but if it is assumed that those observed are due either directly or indirectly to ejected nuclear material⁴, then observable consequences might survive for $\geq 10^8$ yr (ref. 13). The exact timescale must ultimately depend on the nature and viscosity of the interstellar medium, and for the purpose of the present estimate it will be assumed that $\tau_0 \leq 5 \times 10^8$ yr represents a reasonable upper limit. If the sample of galaxies discussed by Burbidge¹⁴ is indeed unbiased (that is, not selected with nuclear activity specifically in mind), then since about half (excluding Seyferts and barred spirals) display noncircular motions $\tau \sim 5 \times 10^9$ yr, and $R \geq 10$. According to the theory discussed by Clube¹⁵ the very presence of spiral arms is an indicator of recently finished nuclear activity, and if this is accepted then the implied value of R is $R \geq 50$.

The radio luminosities of Seyferts, although not usually comparable with those of powerful radio galaxies, are larger than those of normal spirals by factors of $10\text{--}10^3$ (refs 16–18). It is natural to assume that this difference is a consequence of the nuclear activity, and because relativistic electrons radiating at radio wavelengths have synchrotron half-lives of $\leq 10^4$ yr it might be expected that the effects of their decay could be used as a means of distinguishing single from recurrent activity^{5,19}. However, it is difficult to precisely predict the radio evolution of a post-active galaxy, because the result is sensitive to questions such as the time-dependence of the injection spectrum, diffusion losses, and the magnetic field. It is therefore only possible to conclude firmly that the observations are consistent with the hypothesis of recurrence. For radio sources associated with elliptical galaxies, the structural and spectral evidence favours recurrence more directly, with intervals of $< 10^8$ yr (ref. 19) and independent evidence relating to star formation in these galaxies can also be interpreted as evidence for recurrence³.

Our discussion has been confined to apparently normal post-active galaxies. Another estimate of R may be obtained by considering the Seyfert phenomenon itself. This occurs in $\sim 1\%$ of spirals, giving $\tau \sim 10^8$ yr, while the characteristic timescale associated with the velocities ($\sim 10^3$ km s⁻¹) and sizes (~ 1 kpc) of the disturbed central regions of Seyfert galaxies indicate $\tau_0 \sim 10^6$ yr. Thus $R \sim 100$.

We conclude that the available data are not at variance with recurrent nuclear activity, and estimate a mean interval between active periods $\sim 10^8\text{--}10^9$ yr. The analysis below applies particularly to Seyfert activity, the kind most likely to be associated with our own Galaxy. The known properties of our Galaxy can thus serve as a comparatively secure basis for calculation.

The physical basis for recurrence: disk formation

Several authors^{1,3,20} have suggested that material lost from stars undergoing normal stellar evolution represents an inevitable supply of gas from which to fuel nuclear activity. If the stars in the galaxy have any residual angular momentum, the gas will in the first instance flow inwards to form a dense gaseous disk, and the idea that formation of a disk is a necessary step in the creation of an active nucleus has frequently been advanced^{21–23}. If this material is ultimately to collapse into the nucleus it is necessary that it lose both energy and angular momentum; and the long timescales associated with angular momentum transport in astronomical systems²¹ suggest that any theory capable of explaining recurrent nuclear activity must use only stellar mass loss from those relatively low angular momentum stars comprising the bulge components of galaxies.

We first show that this source of gas is sufficient to fuel the Seyfert phenomenon. The stellar mass loss rate from a nuclear star cluster of mass M_n and age t may be shown^{24,25} to be

$$\alpha_* M_n \sim 10^{-2} M_n t^{-1} \quad (1)$$

and adopting $t \sim 10^{10}$ yr and $M_n \sim 10^{10} M_\odot$ (values appropriate for our own Galaxy²⁶), this becomes $\alpha_* M_n \sim 10^{-2} M_\odot \text{yr}^{-1}$. At early epochs ($t \leq 10^9$ yr, say) the mass loss rate is slightly higher than that given by (1), and a more detailed calculation²⁷ shows that the total fractional mass loss during 10^{10} yr is of the order of 10%. The cumulative stellar mass loss in $\sim 10^{10}$ yr in the nuclear region of our Galaxy ($r \leq 1$ kpc) is therefore $\sim 10^9 M_\odot$. The total mass-energy required by the Seyfert phenomenon in this time may be estimated to be $E_s \sim 2 \times 10^6 M_\odot c^2$ (assuming a typical luminosity $L \sim 10^{38}$ W and a cumulative duration for the Seyfert phenomenon of the order of 10^8 yr), so even if energy is released at only 'nuclear' efficiencies ($\sim 0.7\%$) the postulated source of gas is still sufficient to fuel Seyfert activity.

An important objection to a model in which nuclear activity is fuelled by stellar mass loss is that supernovae in the nuclear star cluster might heat the gas up to such high temperatures that a steady outflowing galactic wind would occur²⁸. It should be emphasised that this conclusion is only valid provided that heating dominates cooling, and that the system contains no sink²⁹. In the present problem it has been shown³⁰ that steady winds are only favoured in elliptical galaxies at epochs $t \geq 10^9$ yr, with the flow at earlier times being thermally unsteady and directed inwards. The question as to what sort of flow is eventually achieved depends crucially on what happens at time $t \sim 10^9$ yr, since then (when a steady wind first becomes favoured) the flow will initially be inwards. If the disk formed by inflowing gas at early epochs is sufficiently massive and dense it will be able to absorb even hot inflowing gas without heating up, and the appropriate solution to the galactic wind equations will then be one including the presence of a massive disk-like sink. Even if supernovae heat the stellar mass loss with high efficiency the flow can continue inwards, and provided that the sink is strong enough we conclude that outflowing galactic winds do not remove material from the central regions of galaxies.

Physical state, structure and evolution of the disk

To account for the observed nuclear activity it is necessary first that the disk survives as a sink, even when (possibly) hot material is falling on to it; and second that the disk evolves in such a way as to store gas for long periods until a sufficient mass has accumulated that a period of nuclear activity might be produced. To verify that these conditions can indeed be met for a very simple model (more detailed arguments are given elsewhere²⁵), it is assumed that the disk has a surface density

$$\sigma(\tilde{\omega}) = \frac{M_d}{2\pi R_d} \frac{1}{\tilde{\omega}} \cos^{-1}(\tilde{\omega}/R_d) \quad (2)$$

where M_d and R_d are the disk mass and radius respectively. It

may be shown that this density distribution would arise in a model in which the disk is formed out of stellar mass loss from a star cluster with density defined (compare ref. 26) by

$$\rho_*(r) = \frac{M_n}{4\pi R_n} \frac{1}{r^2} \quad (3)$$

and in which it is assumed that the net rotational velocity of the stars at equatorial radius $\tilde{\omega}$ is given by $V_{\text{rot}}(\tilde{\omega}) = \text{constant}$. A model with the same star density but uniform rotation would give a somewhat more centrally condensed disk, but the essentials of the argument do not depend on this detail.

If the r.m.s. gas velocity in the disk is V_s , it may be shown^{31,32} that the disk width $H(\tilde{\omega})$, defined as

$$H(\tilde{\omega}) = \sigma(\tilde{\omega}) / \rho(\tilde{\omega}, 0)$$

is given by

$$H(\tilde{\omega}) = \zeta \frac{V_s}{V_0} \tilde{\omega} \quad (4)$$

where ζ is a numerical factor which, for disks that are gravitationally stable, is of order unity, and V_0 is the (constant) circular velocity in the model: $V_0 = (GM_n/R_n)^{1/2}$. The mid-plane particle density is therefore

$$n(\tilde{\omega}, 0) \sim 3 \times 10^9 \left(\frac{M_d}{10^7 M_\odot} \right) \left(\frac{100 \text{ pc}}{\tilde{\omega}} \right)^2 \times \left(\frac{\cos^{-1}(\tilde{\omega}/R_d)}{\zeta} \right) \left(\frac{1 \text{ km s}^{-1}}{V_s} \right)^2 \text{ m}^{-3} \quad (5)$$

where the mean particle mass has been taken to be $m_H \sim 1.7 \times 10^{-27} \text{ kg}$ and the values $M_n \sim 10^{10} M_\odot$, $R_n \sim 1 \text{ kpc}$ and $R_d \sim 500 \text{ pc}$ have been assumed. The disk is thus very dense, even if V_s should be several tens of km s^{-1} , and it may be expected that cooling, proportional to n^2 , will be efficient. In order to estimate the equilibrium temperature of the disk we consider the balance between heating and cooling processes, as represented by the equation

$$\Gamma = n^2 \Lambda(T)$$

where Λ is the usual cooling function and Γ is the power input per unit volume from various sources.

Four sources of heating have been considered as of possible importance for the energetics of the disk: (1) heating due to possibly hot infalling material, (2) heating by stars located within the disk, (3) heating by supernovae within the disk, and (4) heating by the effect of stars passing through the disk. On the assumption that stellar mass loss does not lead to further star formation until the disk becomes gravitationally unstable (so that until the point is reached the system contains no massive O-B stars), it may be shown that heating is dominated by hot infalling material. This heat source may be written in the form

$$\Gamma_1 \sim \epsilon(\tilde{\omega}) \frac{\partial \rho}{\partial t}$$

where ϵ is the excess energy deposited by unit mass entering the disk and $\partial \rho / \partial t$ is given approximately by $1/H \partial \sigma / \partial t$. The energy carried by unit mass entering the disk consists of a thermal part $\epsilon_{\text{th}} \sim 3kT/m_H$, and a gravitational part $\epsilon_{\text{grav}} \sim V_0^2$; so Γ_1 is given approximately by

$$\Gamma_1 \sim \left(\frac{3kT}{m_H} + V_0^2 \right) \frac{1}{H(\tilde{\omega})} \frac{\partial \sigma}{\partial t} \quad (6)$$

By substituting for H and $\partial \sigma / \partial t$ (making use of $(dM_d/dt) = \alpha_* M_n$), and assuming that the infalling material has an initial

temperature $T \sim 2 \times 10^7 \text{ K}$ corresponding to that of a steady supernova-heated flow²⁸, this reduces to

$$\Gamma_1 \sim 7.5 \times 10^{-23} \left(\frac{\alpha_* M_n}{10^{-2} M_\odot \text{ yr}^{-1}} \right) \left(\frac{500 \text{ pc}}{R_d} \right) \times \left(\frac{\cos^{-1}(\tilde{\omega}/R_d)}{\zeta} \right) \left(\frac{1 \text{ km s}^{-1}}{V_s} \right) \left(\frac{100 \text{ pc}}{\tilde{\omega}} \right)^2 \text{ W m}^{-3} \quad (7)$$

Since $\Gamma \sim \Gamma_1$, combining (7) with $n \sim n(\tilde{\omega}, 0)$ gives the value of the cooling function required to just keep the disk at temperature T . That is,

$$\Lambda_{\text{req}} \sim \Gamma_1 / n^2(\tilde{\omega}, 0) \Rightarrow \Lambda_{\text{req}} \sim 10^{-41} \left(\frac{\alpha_* M_n}{10^{-2} M_\odot \text{ yr}^{-1}} \right) \left(\frac{V_s}{1 \text{ km s}^{-1}} \right) \times \left(\frac{10^7 M_\odot}{M_d} \right)^2 \left(\frac{\tilde{\omega}}{100 \text{ pc}} \right)^2 \text{ W m}^3 \quad (8)$$

where as before it has been assumed that $M_n \sim 10^{10} M_\odot$, $R_n \sim 1 \text{ kpc}$ and $R_d \sim 500 \text{ pc}$, and factors of order unity have been dropped. Comparing this with the cooling function appropriate for a lightly ionised atomic disk³³ and assuming that $V_s \sim V_{\text{sound}}$ (since strongly supersonic motions are quickly damped), implies the disk will cool—especially in its central regions—to a temperature $\leq 50 \text{ K}$. It is thus concluded that a representative disk of mass $M_d \sim 10^7 M_\odot$ will be cold, and in its central regions will consist of gas mainly in molecular form. The disk therefore does act as a sink, and is able to absorb all the infalling gas due to stellar mass loss without heating up.

If viscous evolution may be neglected during this phase of the disk's evolution (this is verified below), the disk will slowly grow in mass until the onset of gravitational instability. The critical surface density may be shown³¹ to be given approximately by

$$\sigma_{\text{crit}} \sim \frac{\kappa V_s}{\pi G} \quad (9)$$

where κ is the epicyclic frequency, given by $\sqrt{2}(V_0/\tilde{\omega})$ in the present model. Substituting $\sigma(\tilde{\omega})$ into (9) gives the critical mass at which instability first occurs at radius $\tilde{\omega}$:

$$M_{\text{crit}}(\tilde{\omega}) \sim 2\sqrt{2} \left(\frac{V_s}{V_0} \right) \left(\frac{R_d}{R_n} \right) \frac{M_n}{\cos^{-1}(\tilde{\omega}/R_d)} \quad (10)$$

Use of the previously adopted values of M_n , R_n and R_d thus shows that the disk will first fragment close to the origin when its mass reaches

$$M_{\text{crit}} \sim 4 \times 10^7 \left(\frac{V_s}{1 \text{ km s}^{-1}} \right) M_\odot \quad (11)$$

The onset of gravitational instability in the disk is expected to lead to a burst of star formation, and if some of the newly-formed stars are sufficiently massive to drive strong turbulence in the disk, the associated viscosity will lead to large central flows of matter. The inwards flux of matter across radius $\tilde{\omega}$ may be shown²¹ to be given approximately by

$$F \sim 2\pi\nu\sigma \quad (12)$$

where ν is the kinematic viscosity. This is given roughly by $\nu \sim \frac{1}{3}\bar{c}l$ where $\bar{c}$ is the mean velocity of a turbulent element and l its mean free path²¹. If l is taken to equal the mean epicyclic amplitude of cloud motions, $l \sim \bar{c}/\kappa$, the kinematic viscosity becomes

$$\nu \sim \frac{1}{3\sqrt{2}} \frac{\bar{c}^2}{V_0} \tilde{\omega} \quad (13)$$

The expected central flux of matter just after the onset of gravitational instability is thus

$$F_{\text{acc}} \sim 2\pi r v_{\text{acc}} \sim \frac{2}{3} \frac{\bar{c}^2 V_s}{G}$$

$$\Rightarrow F_{\text{acc}} \sim 0.06 \left(\frac{\bar{c}}{20 \text{ km s}^{-1}} \right)^2 \left(\frac{V_s}{1 \text{ km s}^{-1}} \right) M_{\odot} \text{ yr}^{-1} \quad (14)$$

where $\bar{c} \sim 20 \text{ km s}^{-1}$ has been assumed representative of the mean turbulent velocity in a newly-formed H II region. The flux just before gravitational instability may be estimated from this formula by setting $\bar{c} \sim V_s \sim 1 \text{ km s}^{-1}$, thereby verifying that viscous flows during the quiescent phase of the disk's evolution are indeed small.

If nuclear activity is produced by a period of rapid accretion on to a massive black hole^{2,23,34} energy may be produced with an efficiency, η , approaching 30% (ref. 35). The luminosity generated by such a process is given by

$$L \sim \eta F_{\text{acc}} c^2$$

$$\Rightarrow L \sim 10^{38} \left(\frac{\eta}{0.3} \right) \left(\frac{\bar{c}}{20 \text{ km s}^{-1}} \right)^2 \left(\frac{V_s}{1 \text{ km s}^{-1}} \right) \text{ W} \quad (15)$$

which is very close to the observed luminosities of typical Seyfert galaxies³⁶. From this result we conclude that although other theories of the nature of nuclear activity might be more appropriate (see the discussion), the theory described here is not inconsistent with accretion on to a black hole. Observations of Seyfert galaxies indicate the presence of substantial masses of gas in the nuclear regions^{37,38}, so it is unlikely that normal nuclear activity is able to totally destroy the disk and remove all the gas from the central region. The disk (or parts of it) therefore survives a period of Seyfert activity and the processes described above can be expected to recur, thereby producing a mechanism by which recurrent nuclear activity might be understood.

We note in passing that although conceivable, steady evolution of the disk does not seem likely. For example, it is possible to envisage a steady state in which infall is just balanced by a slow rate of star formation. However, such a situation could only be truly steady if the disk always formed low-mass stars, a possibility that we regard unlikely. The occurrence of even a few massive stars would lead to more³⁹, and eventually turbulent velocities large enough to cause inward fluxes much greater than the infall rate (and sufficient to lead to a period of nuclear activity) would be generated. Massive star formation leads to non-steady evolution. In a different kind of steady state it might be argued (compare ref. 22) that once gravitational instability³¹ has occurred, the heat generated by cloud-cloud collisions and viscous friction could be large enough to maintain a relatively large velocity dispersion in the disk. A steady inward transport at a rate equal to the stellar mass loss rate might then occur, and recurrence (at least on the black hole model) would not necessarily follow. In the present analysis the inward flux immediately after gravitational instability is F_{acc} , implying the viscous heating rate per unit area is given²¹ by

$$D(\tilde{\omega}) \sim F_{\text{acc}} V_0^2 / 2\pi \tilde{\omega}^2$$

Dividing this by the disk width (equation (4)) for a disk with velocity dispersion characterised by turbulent velocities $\bar{c} \gg V_s$ (where V_s is the velocity dispersion just before gravitational instability) gives the volumetric heating rate due to viscous processes, Γ_{visc} :

$$\Gamma_{\text{visc}} \sim \frac{1}{3\pi \zeta} \frac{V_0^2 \bar{c} V_s}{\tilde{\omega}^3 G}$$

that is,

$$\Gamma_{\text{visc}} \sim \frac{5 \times 10^{-24}}{\zeta} \left(\frac{\bar{c}}{10 \text{ km s}^{-1}} \right) \left(\frac{V_s}{1 \text{ km s}^{-1}} \right) \left(\frac{100 \text{ pc}}{\tilde{\omega}} \right)^3 \text{ W m}^{-3} \quad (16)$$

where the usual values of M_0 and R_0 have been assumed. Comparing this expression with (7) shows that viscous heating is unimportant to the energy balance of the disk at $\tilde{\omega} \geq 10 \text{ pc}$, and even at $\tilde{\omega} \sim 1 \text{ pc}$ is only about five times larger than Γ_1 (for $V_s = 1 \text{ km s}^{-1}$ and $\bar{c} = 10 \text{ km s}^{-1}$). The conclusion that the disk will be very cold therefore remains valid, and unless some other energy source intervenes (such as massive star formation) turbulent velocities large enough to drive inward flows of order $\alpha_* M_* \sim 10^{-2} M_{\odot} \text{ yr}^{-1}$ will not be produced. If stars are formed this case reduces to the one above, and steady evolution can only occur if no massive stars form.

Discussion

In the previous sections it has been shown that not only do observations strongly support the idea that nuclear activity in massive galaxies (such as our own) is a recurrent phenomenon, but also this might be rather simply understood by a model in which stellar mass loss leads periodically to nuclear activity via the intermediary of a dense cold (probably molecular) gaseous disk. Arguments based on the rate of viscous transport in the central regions of the disk and the expected evolutionary time-scale of any massive object likely to be formed ($\tau_{\text{evol}} \sim 10^6 \text{ yr}$, say) lead to the conclusion that in the first instance a body with mass in the approximate range 10^4 – $10^6 M_{\odot}$ will be formed (for example, equation (14)). Depending on the detailed evolution of a body of this size, three possibilities may be distinguished.

In the first, it is assumed^{2,40} that any body much more massive than an ordinary star will end its evolution by a period of relativistic collapse, ultimately forming a massive black hole. However, the present theory (based on parameters thought to be typical of our own Galaxy) combined with the observations that the galactic centre does contain large amounts of gas, implies that our Galaxy has undergone recurrent periods of nuclear activity; this is also consistent with the conclusion reached by Lynden-Bell², that the observed numbers of quasars makes it difficult to argue that our Galaxy has never been active. If our Galaxy was active in the distant past, the expected size of the black hole now in its nucleus may be estimated in several ways. First by comparing typical Seyfert or quasar powers with the Eddington limit of a mass M_b ; for $L_{\text{av}} \sim 10^{38} \text{ W}$ this gives $M_b \approx 5 \times 10^6 M_{\odot}$, with much larger masses being indicated if our Galaxy has ever been as luminous as a quasar⁴¹. Second, by dividing E_{av} by ηc^2 , where η may be estimated³⁵ to be ≤ 0.3 ; this again gives $M_b \approx 5 \times 10^6 M_{\odot}$. Third, by assuming growth at an average rate limited by the stellar mass loss rate²³. With $\alpha_* M_* \sim 10^{-2} M_{\odot} \text{ yr}^{-1}$ this gives $M_b \sim f \times 10^6 M_{\odot}$, where f is the unknown fraction of the mass lost by stars actually transported into the origin; and lastly by assuming growth at a rate limited by the stellar tidal disruption rate^{42–44}, giving $M_b \sim 10^4 M_{\odot}$ provided that the initial hole mass exceeded $\sim 10^6 M_{\odot}$. (Lower mass holes do not grow rapidly in normal galactic nuclei by this process, and the estimate is particularly uncertain as it is possible that the net accretion rate may be much smaller than the tidal disruption rate^{45,46}.) Observationally, current data can be understood without appeal to exotic objects such as black holes^{47,48}, and estimates of the mass within a radius of $\sim 1 \text{ pc}$ ($\sim 4 \times 10^6 M_{\odot}$) are consistent with it being mostly in stellar form^{49,26}. Since observational upper limits to the black hole mass are less (albeit close to) than the theoretical lower limits, we tentatively conclude that black holes are not usually formed in galactic nuclei.

This leaves one of two possibilities. Either the body formed at the centre of the disk explodes disruptively when nuclear burning is initiated^{50,51}, or the body does enter a period of relativistic collapse, but does not form a massive black hole. General relativity has yet to be tested experimentally in the relativistic regime, so this possibility should perhaps not be too lightly dismissed on the ground that it invokes 'new physics'. A detailed discussion of this case is given by Clube¹⁵, who argues that a wide range of independent observations of our Galaxy can be understood most simply on a model in which the Galaxy periodically grows a nucleus whose late evolution does require new physics for its explanation. Here we consider the more conventional

possibility, and note that although the evolution of low-mass supermassive stars as described by Fricke and others does not seem capable of explaining the high luminosities of Seyferts and quasars (approaching in some cases up to $\sim 10^{41}$ W), the nonthermal radiation of a spinar can in some circumstances far exceed the thermal (Eddington-limited) component⁵². It seems likely therefore that the disk will in the first instance form a rapidly rotating disk-like configuration at its centre—resembling a flattened spinar—and although spinar masses are usually assumed to be $\geq 10^8 M_\odot$ (to explain the large energies required by active nuclei for single events), adopting recurrence would lower this requirement considerably. The repeated formation and evolution of low-mass spinars ($M \leq 10^6 M_\odot$) might well explain most nuclear activity, although until the effect on the object of nuclear burning is better understood (that is, whether or not leading to a disruptive nuclear explosion) it is not possible to say with certainty whether 'new physics' is required by the data. It should be noted that stellar mass loss can explain Seyfert energetics even if energy is produced only at nuclear efficiencies.

Thus we have shown here that a wide variety of observational evidence indicates that nuclear activity is a recurrent phenomenon, and that this might be understood on a theory in which activity is caused by gas lost from stars evolving to form an active nucleus via the intermediary of a dense gaseous disk. Following Ozernov and Usov⁵² we conclude that recurrent nuclear activity is best understood by a spinar model, although the present theory indicates that in the first instance only low-mass objects ($M \leq 10^6 M_\odot$) are likely to be formed. Calculation of the late evolution of such a mass depends critically on the effects of the onset of nuclear burning, and our current understanding of this problem does not allow the possibility of gravitational collapse to be distinguished theoretically from that of a disruptive nuclear explosion. From the observational viewpoint the formation of massive compact relativistic objects seems extremely probable⁵³, with one of their most important characteristics being the ejection of both matter and energy⁵⁴.

The hypothesis of recurrence places severe constraints on theories of the origin of nuclear activity. In particular, the apparent lack of a supermassive black hole in our galactic centre argues against the black hole theory, although it should be emphasised that this conclusion does not affect the discussion in the main part of the paper. Because of its potential to discriminate between theories of nuclear activity, further work aimed at distinguishing recurrence from single activity should be given high priority.

We thank our colleagues, particularly Dr P. W. J. L. Brand, for discussions. M.E.B. was supported by a grant from the Cormack Bequest of the Royal Society of Edinburgh.

Re-appraisal of lithostratigraphy of Sterkfontein hominid site

T. C. Partridge

5 Inverness Road, Westdene 2092, South Africa

A new lithostratigraphic classification is proposed for the Sterkfontein hominid site. The Sterkfontein Formation is defined in terms of constituent members and beds. The new terminology is correlated with that used previously and, where possible, hominid finds are linked to the newly defined lithostratigraphic units.

THE stratigraphy of the rich site at Sterkfontein, where *Australopithecus africanus* was discovered in 1936, has been investigated several times. Between 1938 and 1952 several

broad descriptive classifications of the deposits were proposed^{1–4}. The first detailed stratigraphic and sedimentological analysis appeared in 1958 (ref. 5); this supplemented by a further generic re-appraisal of portions of the succession⁶, has provided the standard lithostratigraphic subdivision of the deposit until recently. A subsequent geomorphological study of the Sterkfontein cave system⁷ included some deposits. A re-appraisal of the lithostratigraphy of the hominid deposit is necessary because earlier stratigraphic studies did not examine its full vertical extent; the application of contemporary sedimentological measures and stratigraphic classification procedures also seems desirable. In this article I call the hominid-bearing deposit the Sterkfontein Formation.

Location and origin

The Sterkfontein Formation is the largest continuous cave filling at the site ($26^{\circ} 01' S$, $27^{\circ} 44' E$), and is vertically and laterally continuous through both the Type and Extension sites. It has been exposed both at surface and in the underlying cave system by excavations at elevations of 1,460–1,480 m. At surface the deposit measures approximately 75×15 m. It is exposed on the southern flank of the Sterkfontein hill, the top of which is about 2 m above the highest exposure.

The formation occurs in disconformable juxtaposition with the Malmani Dolomite⁸ of the Transvaal Supergroup, having accumulated within a karst cavity. The sedimentary sequence has been modified periodically by subsidence into underlying cavities formed or enlarged after accumulation of the deposits, by collapse of the cavern walls and roof, by the introduction and dissolution of calcium carbonate cement, and by bevelling of the succession by erosion of the valley flanks of the Bloubaank river (formerly Blaaubank). The Malmani Dolomite here consists of an interbedded succession of dolomite and chert horizons.

The formation of the original solutional receptacle and its subsequent morphological development conform closely with the model of karst development under a spasmodically falling water table proposed for the Transvaal⁹. This initial cavern owed its form to phreatic solution, but was modified by enlargement and collapse in the vadose zone; these modifications were often contemporaneous with the accumulation of the cave filling. The form of the receptacle was controlled by preferential solution along joints and small faults and within locally more soluble horizons in the dolomite, which here dips at approximately 30° NNW. The water table occurs in the underground cave system below the base of the Sterkfontein Formation at an elevation of approximately 1,440 m. Deposits postdating the Sterkfontein Formation are discontinuously present from surface down to this level, and, in places, display complex disconformable relationships with certain of its members.

Although relatively extensive areas of dolomite roof are preserved over parts of the deposit, much of its surface has been bevelled by erosion of the hillside. The inclinations of the lower surfaces of roof segments conform with the local dip of the dolomite bedding planes; a projection of these remnants gives an indication of the maximum elevation of the original roof, which was probably situated some 10 m above the southern part of the deposit. Hence the absolute thickness of the deposit may have exceeded 30 m, less than 70% of which is still preserved.

The original floor of the receptacle varied considerably in elevation; the thickness of the various sedimentary members is very variable and the irregular shape of the depository and obstructing roof pendants produced local variations in the direction of sediment transport. Stratigraphic relationships are consequently complex, and the schematic column in Fig. 1 merely reflects the relative average thicknesses of the various units in accessible areas of the deposit.

Lithostratigraphy

Laboratory analyses were made of large samples (> 5 kg) from average vertical separations of < 2 m, recovered, as far as possible, from three sampling areas. The procedure involved colour identification using Munsell soil colour charts, removal of CaCO_3 in 10% cold dilute HCl, wet sieving and hydrometer analysis of the residue between 1 and $2,000 \mu\text{m}$ at average mesh size intervals of 0.5ϕ (using sodium hexametaphosphate as a peptising agent), plotting of cumulative textural curves, calculation of Trask indices and statistical parameters using the formulae of Folk and Ward¹⁰, examination of the medium sand residue under a $\times 40$ binocular microscope, and X-ray diffraction analysis of the $-75\text{-}\mu\text{m}$ particle size fraction from selected samples.

The very coarse (> 2 mm) fraction of all units was examined visually, and consists chiefly of subangular fragments ranging from pebble to boulder size. The smaller (pebble to cobble) fraction predominates in Members 2 and 6, while large cobbles

Fig. 1 Stratigraphic column of the Sterkfontein Formation (see text for details)

and boulders are characteristic of bed C of Member 4. In the case of Members 2 and 6 these coarse elements consist almost exclusively of chert, which has sometimes suffered extensive post-depositional snuffbox weathering. In the other units both chert and dolomite are represented; individual fragments, particularly in the larger fractions, are mostly fresh, but may show thin weathering skins on one or two faces, indicating that they accumulated through intracavernous collapses of the roof and projecting ledges. The finer fractions frequently include subrounded chert elements, which are more uniformly and deeply weathered; these represent an extracavernous colluvial component of the deposit. Only in bed B of Member 4 does weathered dolomite contribute significantly to these colluvial elements.

Member 1 is exposed above the weathered dolomite floor in Silberberg Grotto. It consists of 0.5–2.0 m of white banded pale brown (10 YR 7/3) recrystallised meso- and macrocrystalline calcite, locally contaminated with fine clastic sediment. The lower 50%, constituting bed A, has little contamination and no bone. Bed B includes numerous angular chert and dolomite pebbles and cobbles and occasional bone fragments, indicating a small surface opening. The upper contact is wavy and gradational.

Member 2 is exposed in Silberberg Grotto. It consists of 0.5–5.0 m of light brown and red (7.5 YR 6/4–2.5 YR 5/6), mostly centimetre-bedded silty loam (slightly clayey sand-silt) containing numerous broken speleothems, occasional calcite lenses, scattered pebbles and cobbles, and high concentrations of bone near the base. Deposition has occurred around a large stalagmitic boss belonging to Member 1; to the east, bedding planes dip approximately 10° SE, while to the west, the sediments comprise a steep debris cone. CaCO₃ averages 73% and average ϕ mean is 5.20. Sediments are poorly to very poorly sorted¹¹ and highly leptokurtic with pronounced negative skewness. Crystalline minerals (in decreasing abundance) are quartz, pyrophyllite, sericite, goethite and kaolinite. Typical particulate roundness and sphericity are 0.1 and 0.5 respectively, indicating higher angularity than is characteristic of present external colluvial soils. As in all succeeding units, quartz particles predominate; chert is present in very small proportions and dolomite grains are rare. Surface staining is largely absent. Contact is slightly wavy and abrupt.

These features suggest periodic ponding and episodic subaqueous deposition with flushing of some fines into more distant depositories to the east of the boss, and conical gravitative accretion to the west. Sedimentary parameters suggest higher energy conditions near the middle of the bed. Distribution of this and succeeding members, and direction of depositional dip relative to relief in cave floor, indicate the presence of an opening vertically above the eastern end of Silberberg Grotto.

Member 3 consists of beds A and B. Bed A is exposed in Silberberg Grotto and is composed of recrystallised mesocrystalline calcite averaging 0.5 m thick and dipping about 15° SE. Bed B is exposed in Silberberg Grotto and the East Pit of the Type Site (top of bed only). It consists of about 10 m of reddish brown (5 YR 5/4) occasionally speckled red (5 YR 5/8) loam (clayey silty sand) containing scattered angular pebbles, cobbles and boulders and abundant bone fragments. Bedding is not discernible, but calcite lenses occur in lower levels. CaCO₃ averages 76% and average ϕ mean is 5.10. Sediments are very poorly sorted, leptokurtic and very positively skewed. Crystalline minerals are quartz, goethite, sericite, feldspar and kaolinite. Typical roundness and sphericity are 0.3 and 0.5 and compare with outside colluvium. There is occasional pyrolusite staining. Contact is apparently conformable and abrupt. The sedimentology indicates slow, uniform gravitative accretion of external colluvium and, possibly, some aeolian sand through small openings without significant resorting by water, but with occasional collapses of protruding cave ledges.

Member 4 consists of beds A, B, C and D. Bed A is exposed in the Type Site and the Lower Cave. It consists of 1–5 m of

angular pebbles, cobbles and boulders cemented by recrystallised meso- and macrocrystalline calcite, containing occasional small irregular pockets of reddish brown (5 YR 5/4) silty loam (slightly clayey silty sand) and occasional bone fragments. Fine sediments were apparently contemporaneous with the coarse fraction, and are similar to those of bed B, with a ϕ mean of 4.90. Contact is indigitating. This bed indicates a series of major roof collapses in rapid succession, greatly enlarging the cave opening. This is supported by analysis of the ¹³C content of the calcite within succeeding units; a significant increase in ¹³C above this level suggests greatly improved ventilation of the cave¹².

Bed B is exposed in the Type Site, the Lower Cave and lower levels of the Extension Site. It consists of 1.0–5.5 m of predominantly reddish brown (5 YR 4/4 and 5/4), but less frequently yellowish red (5 YR 5/6) and red (2.5 YR 4/6 to 5/8) sandy loam (slightly clayey silty sand) containing abundant pebbles, cobbles and boulders and occasional bone fragments. Crude stratification is present in the very coarse fraction, parallel to the flanks of a debris cone with its apex near the southern margin of the Type Site excavation. Infrequent recrystallised calcite lenses occur on the flanks of the cone. CaCO₃ averages 53% and average ϕ mean is 4.47. Sediments are poorly to very poorly sorted and leptokurtic with a wide range of skewness from negative to positive. Near the cone periphery (for example, in the Lower Cave) sediments are less negatively skewed and less markedly leptokurtic. Crystalline minerals are quartz, goethite, sericite and kaolinite. Typical roundness and sphericity are 0.3 and 0.5, and particles often show pyrolusite staining. Contact is eroded and disconformable.

The characteristics of this bed are consistent with discontinuous redistribution of gravelly colluvium, in admixture with roof collapse debris, down the flanks of a cone of gravitative accretion under the influence of sheetfloods entering through an enlarged cave opening. Higher energy conditions are evident towards the middle of this unit, especially around the periphery of the cone.

Bed C is exposed in several large, isolated pockets in the Type Site and the Lower Cave. It consists of 0.5–2.0 m of yellowish red (5 YR 5/6) or red (2.5 YR 4/8) unbedded sandy loam (slightly clayey silty sand) containing occasional angular cobbles and boulders and localised concentrations of bone. CaCO₃ averages 53% and average ϕ mean is 4.11. Sediments are very poorly sorted and mesokurtic to leptokurtic with marked negative skewness. Crystalline minerals are quartz, sericite, kaolinite and goethite. Typical roundness and sphericity are 0.3 and 0.5, and pyrolusite staining is common. Contact is even and abrupt.

There seems to have been greater dominance of water action than in bed B, with flushing out of fines. The gravelly component of the external colluvium (if present) was not introduced during

Table 1 Comparative terminology of Sterkfontein Formation

Fig. 2 Locality plan showing the surface extent of the Sterkfontein Formation and the positions of localities mentioned in the text. (After A. R. Hughes.)

this period; and intracavernous collapses were less frequent. Higher energy conditions prevailed during deposition in the middle of this unit.

Bed D is exposed in the Type Site and the Lower Cave, vertically above pockets of bed C. It consists of discontinuous white, to brownish (10 YR 5/3) horizontally laminated, recrystallised meso- to macrocrystalline calcite lenses up to 75 cm thick. These consist of accumulations of thin calcite rafts which occasionally form in pools in contemporary Transvaal caves. Contact is unconformable and eroded; there has been minor subsidence of Member 4 before accumulation of Member 5.

This bed represents a period of greater abundance of water in the cave. The presence of very large collapse blocks incorporated in the calcite cement indicates another episode of roof instability.

Member 5 is exposed at the Extension Site and the western end of the Type Site. It consists of 1–5 m of reddish brown (5 YR 5/4 and occasionally 4/4) sandy loam (slightly clayey silty sand) containing numerous pebbles, cobbles and boulders, mostly of chert and dolomite, but including foreign quartz, quartzite and diabase, which are believed to have been introduced by hominids¹³. Bone is occasionally present, and a few calcite lenses occur near the middle of the member. Crude bedding, mostly conformable with the eroded surface of Member 4, is evident in the very coarse fraction. CaCO_3 averages 54% and average ϕ mean is 3.85. Sediments are very poorly sorted and meso- to leptokurtic with negative skewness. Crystalline minerals are quartz, goethite, feldspar, sericite and kaolinite. Roundness and sphericity are similar to those in Members 3 and 4, but pyrolusite staining is less frequent. Contact is abrupt, eroded and unconformable.

The mode of accumulation was as in bed B of Member 4, but without the introduction of weathered dolomite colluvial gravels. Differences in the range of skewness can be ascribed to the relative positions of exposures within the depositional cone. The configuration of crude stratification confirms the location of the main cave entrance to the south of the Type Site. Evidence of cyclically higher energy conditions is present near the middle of this member.

Member 6 is exposed on the north wall of the West Pit excavation in the Extension Site. It consists of beds A and B. Bed A is composed of up to 25 cm of contaminated and recryst-

allised basal calcite, which is occasionally bone-bearing. Bed B is 0.5–1.0 m of dark reddish brown (5 YR 3/3) sandy loam (clayey silty sand) containing occasional pebbles and cobbles, including foreign stone and some bone. A single sample from bed B had a CaCO_3 content of 47% and a ϕ mean of 5.10. Sediments are very poorly sorted out and highly leptokurtic with positive skewness. Crystalline minerals are quartz, sericite, kaolinite, goethite and feldspar. Roundness and sphericity are 0.5 and 0.7 and a large proportion of particles shows pyrolusite staining.

Bed B is similar to the pebbly colluvial soils which now occur on adjacent areas of the Sterkfontein hill; however, foreign stone is absent from the latter, and sand grains of Member 6 are less angular.

Extracavernous source materials

Comparative analyses of deposits from the vicinity indicate that the –2-mm fraction of the various units was derived overwhelmingly from extracavernous colluvial sources. The contribution of the insoluble residue produced by intracavernous corrosion is chiefly restricted to a few highly angular chert particles.

Several generations of colluvium are evident near Sterkfontein; these range from the pebbly, skeletal mantles in areas where a balance exists between erosion and deposition, to less frequent, deeper, pedogenetically differentiated profiles in relict areas immune from rapid denudation. The –2-mm fractions usually display fairly similar ranges of properties; these seem related rather to a geomorphic environment of episodic incision along the Bloubaank valley and to local depositional conditions than to climate and weathering, the imprint of which should rather be sought in fluctuations in patterns and rate of sedimentation within the protected environments of cave depositories.

The characteristics of the Sterkfontein Formation are most readily explained in terms of the reworking of source materials akin to the present, widespread, thin, pebbly colluvium. This is a dark reddish-brown (5 YR 3/4), sandy loam (slightly clayey silty sand), containing abundant weathered chert pebbles and cobbles, and seldom exceeding 50 cm thick. The ϕ mean averages 4.20. The material is poorly to very poorly sorted and is leptokurtic with a small range of skewness, both negative and

positive. Crystalline minerals are quartz, goethite, kaolinite, sericite and feldspar. Roundness and sphericity are 0.3 and 0.5, and many particles show pyrolusite staining.

Sedimentary facies of the various units of the Sterkfontein Formation can be related to the extracavernous colluvium in terms of a limited suite of transportation and depositional processes. Except in the case of Member 3, where enrichment in fines, possibly due to the presence of an aeolian component, has resulted in pronounced positive skewness, the colluvial source materials have suffered removal of fines to various degrees. This can be attributed to the flushing action of successive sheetfloods through the cave opening, which tended to transport fine elements into more distant depositories within the cavernous dolomite, increasing negative skewness except where further transportation was obstructed (for example, in areas where debris cones impinged on the walls of the cave).

Fine sedimentary fractions are more abundant in the lower members, due to the greater degree of illuviation with increasing distance from the cave opening. An exception is Member 6, the proximity of which to the cave opening would be expected to favour a depletion in fines through flushing and eluvial effects. The relatively high proportion of fines encountered in this member suggests that the colluvial source materials have undergone limited transportation into a restricted depository with enrichment in fine elements.

The extensive hiatuses in clastic deposition within the cave, sometimes associated with calcite accretion, indicate cycles with reduced influx of extracavernous sediments. In some instances such episodes were marked by intra-cavernous scouring and the production of erosional unconformities.

Under the present climatic and pedogenetic regime in the area the very coarse fraction of the colluvium consists exclusively of partially weathered chert fragments derived from the chert-rich dolomite. Material of this type is present in all members, and has sometimes undergone post-depositional weathering. Only in bed B of Member 4 does weathered dolomite form a significant component of the very coarse colluvial fraction. The contemporary occurrence of weathered dolomite in colluvial mantles in South Africa is restricted to arid environments.

Solution cavities and discrimination between members

Mention must be made of the unconsolidated fillings of solution cavities which were formed within the soluble surface of the Sterkfontein Formation, chiefly of Member 5, after the cessation of sedimentation. These attain depths in excess of 5 m and contain material produced by decalcification and *in situ* weathering of the surrounding sediments. A clear transition exists between the overlying recent colluvium and these residual materials. The latter sometimes contain bone. The weathering residue from Member 5, which occurs within these cavities, is sedimentologically similar to its parent material, but somewhat better sorted, indicating enrichment in fines, either through *in situ* weathering and comminution of particles, or through illuviation from the overlying colluvium. Individual particles are also more rounded than those from Member 5, and pyrolusite staining is widespread.

Sedimentological analysis of samples from the various lithostratigraphic units of the Sterkfontein Formation reveals that successive members are distinctive in terms of the standard deviation of at least one of the associated quartile and moment measures.

Comparison with Swartkrans Formation

The stratigraphy of the nearby Swartkrans hominid site has been re-appraised recently^{14,15}, and the Swartkrans Formation has been defined. Comparison of the Sterkfontein and Swartkrans Formations shows that, although similarities exist, there is no obvious lithostratigraphic overlap between their various members and beds. The sediments of the Swartkrans Formation are distinctly more positively skewed and are generally more

poorly sorted than those of the Sterkfontein Formation. While the accretion of Member 1 of the Swartkrans Formation in a gravitative debris cone is analogous to that of Members 4 and 5 of the Sterkfontein Formation, the subsequent large-scale corrosion of this accumulation, and the filling of the voids thus created with younger sediments, followed, in turn, by a second cycle of channel erosion and deposition, is not apparent at Sterkfontein. The preponderance of sediments derived from deep argillaceous colluvium in both Members 1 and 2 of the Swartkrans Formation¹⁴ likewise has no parallel at Sterkfontein.

The faunal assemblage from the Type Site at Sterkfontein (labelled StS) is overwhelmingly derived from Member 4 of the Sterkfontein Formation; it is very different from that of the Extension Site, and has no equivalent at Swartkrans¹⁶. Previous evaluations of the assemblage from the Sterkfontein Extension Site¹⁷⁻²⁰ have assumed that the entire West Pit assemblage (labelled SE) belonged to one stratigraphic unit. My studies reported here, confirmed independently by C. K. Brain, reveal that some specimens from this assemblage have attached matrix belonging to Members 4 and 6 of the Sterkfontein Formation, even though Member 5 is the most widespread stratigraphic unit exposed in the West Pit. In view of this discovery, previous evaluations of these faunas with respect to chronology will have to be revised. A much needed comparison of the faunas of Member 1 of the Swartkrans Formation and Member 5 of the Sterkfontein Formation awaits a further study of the revised assemblage from the latter unit (to be undertaken shortly by E. S. Vrba).

The fauna from Member 2 of the Swartkrans Formation¹⁵ includes elements from both the main mass of this unit and the later channel fillings. Vrba's¹⁶ earlier and later subdivisions of the SKb bovid fauna can be equated with these two units. Vrba^{16,21} has concluded that the later SKb fauna corresponds to her later Sterkfontein category, which is likely to belong to Member 6 of the Sterkfontein Formation.

These comparative faunal data are not sufficiently precise to permit postulation of time-equivalence between the respective stratigraphic units.

Correlation with previous terminology and hominid finds

It may prove useful for readers familiar with the published stratigraphic terminology of previous workers at Sterkfontein to have a cross-reference to the terminology used here (Table 1). At the same time, an indication is also provided of the relative position of the excavations carried out to date and the known of likely provenance of certain of the hominid remains.

From the above correlation it will be clear that excavations so far have sampled only the uppermost 30% of the stratigraphic thickness of the Sterkfontein Formation. No excavations have been carried out in Members 1-3.

I have not considered biostratigraphic or chronostratigraphic aspects of the Sterkfontein Formation here; these, together with the environmental implications of the data, will be discussed elsewhere.

I thank the University of the Witwatersrand, especially the Department of Anatomy and the Bernard Price Institute for Palaeontological Research, for access to the site. Professor P. V. Tobias and Mr A. R. Hughes for comment and encouragement, and Drs C. K. Brain, E. S. Vrba and A. J. Tankard for useful discussion.

Neuronal properties underlying processing of visual information in the barnacle

Ann E. Stuart & Donata Oertel

Department of Neurobiology, Harvard Medical School, Boston, Massachusetts 02115, and Marine Biological Laboratory, Woods Hole, Massachusetts 02543

Generation of a transient, amplified response to the dimming of light in the visual system of the barnacle involves two synaptic stages. It is accomplished primarily by decrementally conducting neurones that are similar to bipolar cells of the vertebrate retina.

THIS work is concerned with the fate of visual information as it is processed by the first few cells of the simple visual system of the barnacle. The specific problems addressed here have been raised by observations on the vertebrate retina. As information is passed from the receptors to bipolar cells and from them to the retinal ganglion cells, the steady responses that encode light intensity are essentially lost, whereas responses to changes in intensity are amplified. How the synaptic and membrane properties of decrementally conducting retinal cells accomplish this process of differentiation, which enables ganglion cells to perceive changes over a wide intensity range, is not understood (see, for example, refs 1–4). Like their counterparts in the vertebrate retina, the first few cells of the visual pathway of the barnacle are specialised to extract information about changes in intensity.

Voltage changes induced by light in the dendrites of the photoreceptor cells of the barnacle median eye spread decrementally along the cells' axons to their terminals in the supra-oesophageal ganglion^{5,6}. Light depolarises the photoreceptors and dimming causes them to repolarise. In cells which we conclude to be second- and third-order, however, dimming causes a transient depolarisation. This depolarisation generates a burst of action potentials in the third-order cells. These impulses are conducted through the circum-oesophageal connectives to the ventral ganglion to influence neurones that mediate the shadow-induced withdrawal of the animal into its shell^{7,8}. The present study is of the synaptic connections and membrane properties of the neurones that process the receptor signal to generate an 'off-response' over a wide range of light intensities.

Identification of second- and third-order ganglion cells

Many of the neurones of the supra-oesophageal ganglion respond to the dimming of light, and are probably involved in the complex defensive response of the animal to a shadow^{9,10}. Most cells do not respond to the onset of a pulse of light but only to its termination. Certain small cells near the photoreceptor terminals, however, respond to the onset as well as to the termination of light^{11,12}; at light onset these cells hyperpolarise, and at the termination of light they depolarise transiently. As these 'biphasically responding cells'¹³ sense both the onset and

the offset of light, they must precede other cells in the visual pathway. Indeed, their hyperpolarising and depolarising responses, as well as the photoreceptor responses, are spared when sodium action potentials are eliminated by tetrodotoxin (TTX), abolishing all activity in other ganglion cells.

We have investigated further the properties of biphasically responding cells and have found that they can be divided unambiguously into two types on the basis of their characteristic responses to light, their dark resting potentials, and their ability to generate sodium- or calcium-dependent action potentials. So far we have found only one cell of each type on each side of the ganglion.

The responses of a photoreceptor and of each type of ganglion cell to pulses of dim and bright light are presented in Fig. 1. The response of one type, the 'inverting cell' (I cell), is essentially a mirror-image of that of the receptor. Evidence that the I cell is a second-order neurone, in other words directly postsynaptic to the photoreceptors, will be presented below. The I cell displays a low resting potential in the dark (mean -45 mV; range -30 to -50 mV; $n=9$), a marked hyperpolarisation at the onset of light, and a depolarisation or oscillations at the termination of the light pulse. The second type of biphasically responding cell

Fig. 1 Responses to light of a photoreceptor, an I cell and an A cell. *a*, Responses in normal saline to dim (left-hand traces) and moderately bright (right-hand traces) pulses of light of 2 s duration. I cell record is atypical in that most I cells generate off-responses, even following bright lights, which consist of a single depolarisation overshooting the dark resting potential, rather than of the multiple oscillations shown here. *b*, Responses of the same cells shown in *a* when the ganglion was perfused with TTX 10^{-6} g ml⁻¹. The photoreceptor impulse was lost after changing solutions. The recordings from the photoreceptor and I cell were made simultaneously; the A cell responses are from another experiment. Light intensities (log mW cm⁻²) are indicated to the right of the shutter monitor trace (lower trace).

Fig. 2 Conductance of the I cell increases during its response to light. The experiment is illustrated at the top right. Two oscilloscope sweeps are superimposed. The voltage response to a flash of light was recorded by one sweep; short pulses of current of constant magnitude were superimposed on the flash response on the other sweep. The changes in voltage evoked by these current pulses were larger and had a longer time constant in the dark (for example, A) than during the light response (for example, B). To obtain a value for the time constant of the membrane during light and dark independent of bridge balance, a phase-plane plot was made relating the rate of change of the voltages (dV/dt) in pulses A and B to the voltage (V). Ordinate, dV/dt , measured as the difference between voltage measurements at 2 ms intervals during the rising phase of the hyperpolarising pulse (diagram, lower right). Abscissa, V , membrane potential of cell (see diagram). The exponential increase in the negative voltage in time is described by $V = V_{\infty}(1 - \exp(-t/\tau))$ where V_{∞} is the voltage developed at the end of a long current pulse and τ is the time constant. To relate V and dV/dt , one can take the time derivative of the above expression: $dV/dt = (V_{\infty}/\tau) \exp(-t/\tau)$. These two expressions can each be solved for $V_{\infty} \exp(-t/\tau)$ and equated. Therefore $dV/dt = -V/\tau + V_{\infty}/\tau$. This equation describes the lines drawn through the data points on the phase-plane plot by linear regression. From the slopes of each line the time constants of rise of pulses A and B were calculated using the above equation and are shown. As the time constant is inversely proportional to the conductance of the cell, the conductance is increased by a factor of about two.

has been called an 'amplifying cell' (A cell), as the most conspicuous feature of its response is a large depolarisation after termination of illumination even when the concurrent voltage changes in the receptors and I cells are small. The A cell has a resting potential (mean -64 mV; range -55 to -70 mV; $n = 17$) more typical of ganglion cells and the photoreceptor itself; it gives only a small hyperpolarisation to light, but a large depolarisation which sets up action potentials after termination of illumination. Previously published work has dealt with neurones with the properties of A cells¹¹⁻¹⁴ and has shown that impulses arising in these cells at the termination of a light pulse are conducted along the cells' axons in the contralateral connectives.

The hyperpolarising and depolarising responses to light of both I cells and A cells are preserved in TTX (Fig. 1b). In TTX, the A cell is no longer able to generate action potentials, and its background synaptic activity ceases.

One simple way to account for the observations presented in Fig. 1a and b is that the I and A cells are the second- and third-order neurones in the visual pathway. When depolarised by light, the photoreceptors release inhibitory transmitter on to the I cells, causing them to hyperpolarise. In turn, the I cells, when released from inhibition by dimming or by dark, depolarise and release excitatory transmitter on to the third cell in the sequence, the A cell. This scheme is consistent with the

observation that I cells in the dark rest at a relatively depolarised membrane potential which could cause them to release transmitter constantly. Such a circuit has been proposed by Ozawa *et al.*¹⁴ as one likely way of accounting for their observations on cells with the properties of A cells.

The proposed scheme implies that I cells would have a greater conductance in the light, when they are bombarded with inhibitory transmitter, than in the dark. A cells would display just the opposite properties: a greater conductance in the dark when they are bombarded with excitatory transmitter than in the light. We have found that the conductance of the I cell is indeed increased in response to light (Fig. 2). The conductance of cells with properties of A cells has been measured^{13,14} and was found to be greater in the dark than in the light. The direction of the conductance changes in these two biphasically responding cell types supports the hypothesis that the receptor neurone releases inhibitory transmitter in the light and the I cell releases excitatory transmitter in the dark.

Recordings made simultaneously from an I cell and an A cell show that the I cell is presynaptic to the A cell. Injection of current in the dark into the I cell in either the depolarising or hyperpolarising direction causes a steady potential change of the same sign in the A cell (Fig. 3a). This result would be expected if polarisation of the I cell were increasing or decreasing a steady release of excitatory transmitter from this neurone. The long latency between I cell polarisation and A cell response suggests that transmission at this synapse is chemically mediated. Injection of current into the A cell causes no change in the I cell membrane potential (Fig. 3b). Thus, the I cell is presynaptic but not postsynaptic to the A cell. Hyperpolarising currents injected into the I cell to mimic the effect of light can cause a depolarisation in the A cell at the cessation of the current pulse (Fig. 3c), much like the off-response to light.

Functional membrane properties of I cells and A cells

Both I cells and A cells can display regenerative activity associated with repolarising potential changes in the photoreceptor (Fig. 1a and b). The nature of this regenerative activity is decidedly different, however, in the I cell and A cell.

The activity that one sees in the I cell ranges from oscillations to small, slow (about 20 ms to peak) regenerative events with noticeable inflections on the rising phases. This regenerative activity is insensitive to TTX (Fig. 1b). Hyperpolarising current pulses injected into the cell soma evoke oscillations at the break

Fig. 3 Depolarisation or hyperpolarisation of an I cell causes potential changes of the same sign in the contralateral A cell (upper sets of traces). Polarisation of the A cell does not affect the I cell (lower set of traces). The magnitude of the injected current was measured by recording the command potential which drove the current pump in the d.c. preamplifier. The experiment was carried out in the dark.

of the pulse (Fig. 4). Distinct action potentials of greater amplitude can be evoked if the preparation is bathed in 100 mM tetraethylammonium ion (TEA). This compound generally blocks voltage-sensitive potassium channels, thereby reducing outward potassium currents and allowing inward currents to generate larger voltage changes than in normal saline. The amplitudes and rates of rise of the action potentials generated in the presence of TEA are decreased when calcium is replaced by magnesium. When calcium is replaced by barium in the presence of TTX, an action potential can be generated even in the absence of TEA. Thus, the regenerative activity recorded from the soma of an I cell is due to voltage-sensitive calcium channels.

Fig. 4 Oscillations evoked in the I cell at the break of a hyperpolarising current pulse. Three pulses of increasing amplitude have been superimposed. Upper traces: current monitor, current recorded as in Fig. 3. Lower traces: membrane potential.

The impulses set up in the A cell are, on the other hand, abolished by TTX. A cell impulses are always distinct action potentials rather than oscillations, they are conducted along the cell's axon in the circum-oesophageal connective, and they have the fast rise time (1–2 ms) typical of sodium-dependent action potentials.

Information transfer at the first two synaptic stages

Both the peak and plateau of the I cell response (Figs 1 and 5a and b) grow over a range similar to that of the receptor response (ref. 5, Fig. 4). Thus, information concerning the intensity of maintained light is transferred from the receptor to the I cell. Figure 5a shows that the membrane potential of the I cell is a function of light intensity over a range of about 5 log units. The slope of this relationship varies widely among different I cells for reasons as yet unknown.

Figure 6 shows a simultaneous recording made from a photoreceptor and an I cell. The steep slope of the relationship between intensity and plateau response in this I cell shows that receptor potentials as small as 1 mV cause a response in the postsynaptic cell (Fig. 6a). For voltage changes in the receptor ranging from 1–20 mV, the membrane potential in the I cell was roughly proportional to the membrane potential of the photoreceptor (Fig. 6b).

In contrast to the plateau response of the I cell (Fig. 5a), that of the A cell saturates at about $10^{-3.6}$ mW cm $^{-2}$ (Fig. 5b). According to our hypothesis, the A cell plateau is the resting potential of the cell in the absence of synaptic input; at light intensity dimmer than $10^{-3.6}$ mW cm $^{-2}$, the A cell is depolarised by excitatory transmitter released from the I cell. In brighter lights the I cell seems to be hyperpolarised enough so that it stops releasing transmitter.

The essence of the A cell response to a light pulse is its depolarising off-transient. When the ganglion is bathed in TTX, this depolarisation no longer elicits action potentials and its amplitude can be measured. The amplitude of this off-transient is a function of both the intensity and the duration of the

preceding light pulse (Fig. 5d). The off-depolarisation increases with light intensity for dim lights and saturates at moderately bright light. As the amplitude of this saturated response, and the intensity at which it saturates, depends on the duration of the preceding light as well as on its intensity, information concerning absolute light intensity is not preserved at the A cell stage.

Discussion

The physiological observations presented above suggest that visual information passes serially from the photoreceptors of the median eye to decrementally conducting I cells and from them to A cells. The A cells transmit information about dimming to the ventral ganglion.

At the first integrative stage, the synapse between the photoreceptors and the I cells, the light response is inverted by an inhibitory synapse. I cells respond to changes of membrane potential in photoreceptors as small as 1 mV from dark resting potential (–60 mV). Thus, release of transmitter from the receptor must take place at membrane potentials more negative than those in squid presynaptic terminal¹⁵ and even takes place at the dark resting potential (B. Schnapp, personal communication). Release of transmitter at the well characterised synapses in the squid, lamprey and the hatchetfish nervous systems, is not detectable until the presynaptic cell has been depolarised by roughly 20 mV to about –45 mV (refs 15–17). The input–output relationship of the receptor synapse has therefore been shifted so that release, and by inference calcium entry¹⁸, occurs at more negative voltages.

Fig. 5 Responses to light of I cells (a and c) and A cells (b and d). Plateau hyperpolarisations measured in six I cells (a) and seven A cells (b) just before the end of a 2-s light pulse and plotted as a function of light intensity. c, Peak hyperpolarisations of the I cells plotted as a function of light intensity. d, amplitudes of off-responses in an A cell (▼ in b) as a function of light intensity for light pulses of three different durations as indicated. The experiment illustrated in d was carried out in the presence of TTX.

Responses of the I cell to light also resemble those of bipolar cells of the vertebrate retina. In both, the responses are graded, the onset and termination of light evoke potential changes from dark rest in opposite directions to one another, and neither cell type normally generates all-or-none action potentials. Bipolar cells have been reported to exhibit oscillations in certain conditions^{19,20} which have the appearance of small action potentials but are graded in amplitude. These oscillations in the bipolar cell are similar to those sometimes seen in the I cell and might similarly be due to voltage-sensitive calcium channels.

Fig. 6 Relationship between membrane potentials of an I cell and a photoreceptor recorded simultaneously. *a*, Peak (Δ) and plateau ($\bullet$) hyperpolarisations in the photoreceptor and peak ($\square$) and plateau ($\blacksquare$) hyperpolarisations in the I cell as functions of light intensity. Plateaus were measured at the end of a 2-s light pulse. *b*, Plot of the membrane potential changes induced by light in the photoreceptor against changes in the I cell. The data from *a* are replotted showing relationship of peak ($\square$) and plateau ($\blacksquare$) measurements of light responses from the two cells. Dark resting potentials were -44 mV in the I cell and -60 mV in the photoreceptor. The steepness of the relationship is not significant, as it depends on the exact location of the electrode along the length of the photoreceptor axon (6.6 mm from the ganglion in this experiment). This I cell is represented as $\circ$ in Fig. 5*a* and *c*.

The responses of I cells also share features of second-order cells in insect visual systems. Intracellular recordings have been made from second-order neurones (laminar type I neurones²¹) in lateral eyes of several insects (locust²² and fly²³⁻²⁵) and in the median eye of the dragonfly²⁶. Light responses of second-order cells in these insects resemble light responses in the I cell in that they have a large, transient, initial hyperpolarisation which decays to a plateau.

It is not clear whether second-order neurones in insects generate action potentials. As action potentials have been seen occasionally in these insect cells²⁶, the absence of impulses from intracellular recordings is usually attributed to microelectrode damage^{23,26}. On one occasion, however, we have recorded

action potentials from I cells in normal saline which resembled those recorded from second-order cells of the dragonfly ocellus but which were insensitive to TTX. Perhaps the impulses recorded occasionally in insect second-order cells are calcium-dependent.

At the second integrative stage in the barnacle, the synapse from the I cell to the A cell, the intensity range over which the responses of A cells are graded is narrowed and the off-response is amplified (Fig. 5*b*). When I cells are released from a hyperpolarisation caused by light or by current, regenerative activity is seen. We have shown that this activity reflects the activation of voltage-sensitive calcium channels, and it is reasonable to assume that these channels are at least in part those associated with the release of transmitter. The onset of dark, then, causes depolarisation of the I cell, the activation of voltage-sensitive calcium channels, and the release of transmitter which excites the A cell. The release properties of this synapse are such that the graded portion of the light response is for the most part not transmitted to the third-order cell. The oscillation occurring in the I cell when the light goes off, on the other hand, is transmitted and amplified. The large depolarisation occurring in the A cell at the termination of light generates a burst of TTX-sensitive action potentials.

We have suggested that the I cell constantly releases transmitter on to the A cell in the dark. Like Ozawa *et al.*¹⁴ we have observed that in the dark the A cell membrane potential undergoes greater fluctuations than it does in the light. Ozawa *et al.*¹⁴ suggest that this increased noise arises from fluctuations in the continuous release of transmitter on to the cell in the dark and that in the light transmitter release stops.

We have observed excitatory and inhibitory synaptic potentials on both the I cell and the A cell in various conditions. The role of these inputs is not understood; they might well contribute to the light responses in I cells and A cells. It seems unlikely, however, that a third type of biphasically responding cell would be interposed between the receptor and I cell, or between the I cell and A cell, as in our many impalements of small cells in many preparations we have found only these two types of cells which respond when light is turned on. Final confirmation of our postulated scheme must come from the demonstration of direct contact between the cells with the electron microscope.

We thank J. W. Moore for suggesting the analysis of the data presented in Fig. 2; D. Baylor, P. Desan, D. Edgington and E. Frank for helpful comments on the manuscript; B. Schnapp and L. Timpe for discussions; and D. Yurgelun-Todd for technical assistance. This work was supported by NIH grants EY-01188 and EY-70985 to A.E.S. and a NIH postdoctoral fellowship NS-05758 to D.O.

Evidence for splicing of interrupted immunoglobulin variable and constant region sequences in nuclear RNA

T. H. Rabbitts

MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

Evidence is presented that the mouse light-chain coding sequence is interrupted in a 27S nuclear RNA species, whereas the sequence is continuous in both a 13S nuclear RNA and in cytoplasmic mRNA. The discontinuity of coding regions in the 27S nuclear RNA parallels the situation found in myeloma DNA and indicates, therefore, that the removal of interruptions in the V and C regions occurs at the level of nuclear RNA.

IMMUNOGLOBULIN (Ig) polypeptides consist of variable (V) and constant (C) regions associated in a single molecule. This molecule is synthesised, by the antibody-producing cells, from a single mRNA molecule containing both V and C regions¹. Recent restriction enzyme mapping data^{2,3} on mouse κ class light (L) chains have shown that the germ-line DNA carries the V and C genes separated by an unknown stretch of DNA. Differentiation of antibody-producing cells seems to result in DNA rearrangement such that the V and C genes are moved closer together in the genome^{2,3}. It has been shown, however, that such a rearrangement does not result in a fully contiguous stretch of DNA carrying V and C_h genes in a linear array³ but rather the active κ L-chain gene of myeloma cells contains an interruption sequence at or near the junction of the V and C regions: A similar interruption has also been observed in a mouse myeloma λ L-chain⁴. Therefore, the transcription unit encoding the V and C genes includes material which is not represented in the final mRNA.

Recently, data have been obtained from several other systems, showing the occurrence of discontinuous genes. These appear in adenovirus and SV40 (refs 5–11), ribosomal cistrons^{12–16}, globin genes^{17,18} and ovalbumin genes^{19,20}. One possible route by which this extra material may be removed is during the processing of the nuclear RNA (nRNA) precursors of mRNA. Thus, the entire Ig gene (including the sequence of the interruption) can be transcribed into a large nuclear RNA precursor followed by a process of ligation to form contiguous V and C regions. Alternatively, it is possible that the V and C regions could be transcribed into separate nRNA molecules from which the V and C genes are joined. A completely different type of process might involve the RNA polymerase 'jumping' across the interruption sequence (thereby effectively ignoring it) and generating contiguous sequences in RNA from discontinuous sequences in DNA. We have investigated the arrangement of V- and C- region sequences in the nuclear RNA of MOPC 21 cells and conclude that transcription of the interrupted Ig gene produces a nRNA molecule or molecules in which an interruption occurs at or near the V–C junction. Joining of this V–C interruption, therefore, apparently occurs at the level of nuclear RNA to generate a 13S nuclear RNA molecule with continuous V and C regions.

Characteristics of a 27S nRNA containing L-chain sequences

RNA was prepared from detergent-washed nuclei of mouse MOPC 21 cells, and fractionated on a sucrose gradient following

denaturation in dimethyl sulphoxide (DMSO). An aliquot of each gradient fraction was hybridised with ³²P-labelled L-chain complementary DNA (cDNA) and the single strand-specific S₁ nuclease-resistant radioactivity determined by trichloroacetic acid (TCA) precipitation (Fig. 1). The main peak of hybridisation observed was around 13S but significant hybridisation was found in regions up to about 30S (a minor but reproducible peak

Fig. 1 Hybridisation of L-chain cDNA to fractionated mouse myeloma nuclear RNA. Nuclear RNA was prepared from mouse myeloma P3K cells (MOPC 21)²¹ by a modification of a previous procedure²². 10⁶ cells were lysed in 20 ml 0.5% NP40, 0.24 M sucrose, 10 mM Tris-HCl pH 7.5, 10 mM MgCl₂, 10 mM KCl. The nuclei were pelleted and suspended in 1 ml 0.12 M sodium phosphate pH 6.8, and lysed with 100 ml 8 M urea, 0.24 M sodium phosphate pH 6.8, 1 mM EDTA, 0.5% SDS²³. 10 g hydroxyapatite (Biorad) were added and stirred vigorously for 10 min. The hydroxyapatite plus the DNA was removed by centrifugation (5 min at 1,000g) and the supernatant dialysed exhaustively against 0.25 M NH₄Ac, 1 mM EDTA, 0.5% SDS. RNA was recovered by ethanol precipitation and dissolved in 10 ml 7 M urea, 0.35 M NaCl, 0.5% SDS and 1 mM EDTA. This solution was extracted twice with an equal volume of buffer-equilibrated phenol-chloroform (1:1 v/v) and ethanol precipitated. The recovered RNA was washed twice with 3 M NaAc pH 6.0 (ref. 24) to remove residual DNA, reprecipitated from 100 mM NaAc pH 6.0, and finally dissolved in 1 mM EDTA, 70% DMSO. The solution was heated for 2 min at 70 °C, rapidly diluted with 3 vols 0.5% SDS, 100 mM NaCl, 1 mM EDTA and 10 mM Tris-HCl pH 7.5, and layered on 15–40% sucrose gradients (in 100 mM NaCl, 0.5% SDS, 10 mM Tris-HCl pH 7.5, 1 mM EDTA). Centrifugation was for 5 h at 38,000 r.p.m. in an MSE 6 × 14 ml rotor at 25 °C. The gradients were fractionated into 0.5-ml fractions and 100-μl aliquots were ethanol precipitated with 10 μg *Escherichia coli* DNA plus 2,500 c.p.m. unfractionated ³²P-L-chain cDNA. The recovered precipitate was dissolved in 20 μl 0.3 M NaCl, 10 mM Tris-HCl pH 7.5, 0.5% SDS and 1 mM EDTA and incubated at 70 °C for 16 h. The hybridised cDNA was estimated by TCA precipitation following S₁ nuclease digestion as previously described². The cDNA used in this study was made with MOPC 21 L-chain mRNA and T₂-G₃-T as primer. This primer initiates at the equivalent of residue 205 just within the C region^{25–27}, so cDNA molecules begin with C_h sequences and proceed into the V region. The V+_h cDNA used in Fig. 2 consisted of a cDNA band eluted from an acrylamide gel; this band was about 700 bases long and represents the maximum length transcript which can be obtained from the T₂-G₃-T priming site. Sedimentation is right to left. Pools a and b were selected for resedimentation.

of hybridisation being observed at around 27S). Evidently, therefore, the steady-state nRNA of MOPC 21 cells consists mainly of a species showing a similar sedimentation value to 13S cytoplasmic mRNA. A second species (around 27S) seems to be present in the nRNA but in rather low proportions: this RNA will be approximately two to three times the size of the L-chain mRNA and presumably represents a precursor of the L-chain mRNA. This conclusion is consistent with a recent publication²⁸ which showed that, although a 40S species is the probable initial transcript of the L-chain gene, a 13S species was the predominant L-chain-specific nuclear RNA present, with a 24S minor species also being observed.

We have investigated the spatial arrangement of the V and C regions in these nuclear RNA species with an assay previously used to demonstrate the presence of an interruption in the κ L-chain gene³. This assay consists of electrophoretic determination of the size of ³²P-cDNA, protected from S₁ nuclease digestion, after hybrid formation with DNA or RNA. The rationale of this approach is that cDNA containing V- and C-region sequences would be completely resistant to S₁ nuclease after hybridisation with RNA or DNA in which the V- and C-region sequences are continuous. On the other hand, this cDNA would be only partially resistant to S₁ nuclease when hybridised to RNA or DNA in which interruptions of V and C regions occur. In a previous study³ we found that V + C cDNA (that is, cDNA of about 560 bases in length, made as described in Fig. 1 legend, extending over both C and V regions) was not fully protected from S₁ nuclease when hybridised with myeloma DNA prepared from cells making the specific L-chain. Instead,

we observed a major band of protected cDNA (about 290 bases in length) corresponding approximately to the C region. These results indicated the presence of an interruption at or near the junction of V and C_κ regions and also indicated that the V_κ gene may possess interruption(s), as we failed to detect a cDNA fragment consistent with the expected V-gene length³. This assay provides a convenient method to study nuclear RNA precursors, as the S₁ nuclease protection of V + C cDNA by nuclear RNA will exhibit half protection of the type observed with myeloma DNA (DNA-like protection) if the nRNA precursor contains interruptions of the V and C regions or full protection if the nRNA precursor contains continuous V and C regions.

Figure 2 shows the pattern of S₁ nuclease protection of V + C cDNA (700 bases) obtained by hybridisation with various nRNA gradient fractions (from Fig. 1). The pattern of cDNA protected from S₁ nuclease by hybridisation with cytoplasmic mRNA shows two major bands (slot 3): one band of intact cDNA 700 bases in length (complete protection) and a further band of partial protection around 330 bases. This latter material does not occur when purified 13S L-chain mRNA is used³ and possibly results from a specific processing of the RNA. This protection pattern of the cDNA was also found in the higher molecular weight region of the fractionated nRNA but, in addition to this, a further component was observed, with a peak of sedimentation around 27S. This component consisted of an RNA species capable of only partially protecting the 700-base V + C cDNA (after hybridisation) to yield a protected cDNA fragment around 295 bases. This partially protected cDNA fragment is similar to the 'half protection' which we previously observed with experiments on myeloma DNA (that is, DNA-like protection)³ and presumably reflects interruption sequences present in the 27S RNA which are absent from the 13S mRNA. Therefore, in the nuclear RNA there are apparently two separate components, the first having a sedimentation value around 27S, possessing a DNA-like arrangement of V and C regions, and the second with a value around 13S and partly possessing continuous V and C regions (that is, mRNA-like arrangement of V and C regions). Thus, the primary transcripts of the κ -chain gene seem to possess the interruption which occurs at or near the V- and C-region junction.

Confirmation of interrupted V and C regions in the L-chain 27S nRNA

The sedimentation time used for the nRNA described in Figs 1 and 2 was short so as to display any putative nRNA molecules larger than 27S. The result was that the resolution of the 27S and 13S species was poor, and considerable overlap of the two patterns of S₁ nuclease protection was displayed by the various gradient fractions in Fig. 2. To increase the resolution of these molecules and to characterise the 27S molecule further, the two regions of the gradient shown in Fig. 1 (a and b) were pooled and resedimented after further denaturation in DMSO. The hybridisation profiles of L-chain cDNA with these various fractions are shown in Fig. 3. Both pools a and b, as expected, showed hybridisation with L-chain cDNA at a position consistent with a 13S RNA species, and in addition showed peaks of hybridisation at around 27S (pool a) and 20S (pool b). No hybridisation with L-chain cDNA was observed if the nRNA pools were boiled in alkali before resedimentation. Therefore, the material sedimenting at 27S is indeed a high molecular weight nRNA species containing L-chain sequences. The only 'steady-state' precursor molecule which we observe is the 27S molecule, whereas the nature of the 13S nRNA is more uncertain. This RNA is probably a true nuclear species but could be partly contamination of nuclear RNA by 13S cytoplasmic mRNA.

The pattern of S₁ nuclease protection of cDNA after hybridisation to the resedimented nRNA pools (a₁, b₁, and a₂ + b₂, Fig. 3) clearly shows the difference between the 27S and the 13S nRNA, as cross-contamination of the 27S RNA with 13S RNA

Fig. 2 Pattern of S₁ nuclease protection of L-chain cDNA after hybridisation with fractionated mouse myeloma nRNA. 100- μ l aliquots of fractions 17–23 (from Fig. 1) plus 100- μ l aliquots of cytoplasmic mRNA were hybridised to V + C cDNA as in Fig. 1. Following hybridisation, the nucleic acids were precipitated with ethanol and recovered by centrifugation. The pellets were washed with 70% aqueous alcohol, dried *in vacuo* and dissolved in 20 μ l 0.28 M NaCl, 30 mM NaAc pH 4.5, and 4.5 mM ZnSO₄ (ref. 29). S₁ nuclease digestion was carried out for 1 h at 37 °C. Following digestion, the mixtures were diluted fivefold with 0.2 M sodium acetate pH 5.0, 5 mM EDTA and 20 μ g ml⁻¹ *E. coli* tRNA, and ethanol precipitated. The recovered pellet was washed once with 70% alcohol, dried and dissolved in 20 μ l 95% formamide by boiling for 3 min. The denatured samples were electrophoresed in 4% polyacrylamide gel in 8 M urea and the bands visualised by exposure to prefogged Fuji X-ray film at -70 °C using a fast tungstate intensifying screen. Slot 1 is a marker cDNA fraction of ~280 bases; slot 2 is the unhybridised 700-base V + C cDNA; slot 3 is the S₁ protection pattern of cDNA after hybridisation to cytoplasmic mRNA; slots 4–10 show the S₁ protection pattern of cDNA after hybridisation to gradient fractions 23–17 (that is, fraction 23 is the low molecular weight region of the gradient and fraction 17 is the high molecular weight region).

Fig. 3 Hybridisation profiles of cDNA with resedimented nRNA pools. The regions of *a* and *b* shown in Fig. 1 were pooled and the RNA recovered by ethanol precipitation. The RNA was denatured in DMSO and resedimented as in Fig. 1. Aliquots were taken and hybridised with unfractionated L-chain cDNA as in Fig. 1 followed by estimation of S_1 nuclease-resistant cDNA (TCA-precipitable counts). Sedimentation is right to left. The upper panel shows the hybridisation pattern of pool *a* and the lower panel that of pool *b*. The regions a_1 , b_1 and $a_2 + b_2$ were selected for further study.

was limited after the resedimentation. In addition, this experiment should be viewed in relation to the ability of purified 13S mRNA to protect *V + C* cDNA fully from S_1 nuclease³. Figure 4 shows the size of cDNA protected from S_1 nuclease after hybridisation of *V + C* cDNA (700 bases) to the nRNA pools. Both the 27S (a_1) and 20S (b_1) pools exhibit DNA-like protection patterns in that the major protected component of the *V + C* cDNA (initially 700 bases) was about 295 bases long. (This size estimate is based on a comparison with radioactive *Hae*III digestion fragments of Φ X174 which were run in a parallel slot of the gel.) The principal feature of these protection patterns is, therefore, the ability of the 27S nRNA to yield a protected cDNA fragment of about 295 bases in length which parallels the situation with myeloma DNA. The result, therefore, demonstrates that a sequence occurs in the initial transcripts, of the κ gene, which is absent from the mRNA. A small amount of intact *V + C* cDNA is observed after hybridisation with the 27S nRNA: this material may result from contamination with mRNA-like sequences and/or incomplete digestion of the cDNA. The 13S pool ($a_2 + b_2$) shows a different pattern of protection, yielding two bands of approximately equal quantities (700 and 330 nucleotides) of which the fully protected *V + C* 700-base component reflects the fully integrated state of at least part of the 13S nRNA. There is no evidence that the 295-base component results from hybridisation of cDNA to 13S nRNA, indicating that splicing events have occurred to eliminate this interruption at around the *V-C* junction. The origin of the 330 component is at present obscure, but as we were unable to detect such a component in purified L-chain mRNA³, we feel that the component is derived from nuclear RNA. We are, therefore, investigating the possibility that this material is a consequence of the nuclear RNA splicing which may involve, for example, putative interruptions in the V_κ -gene sequence.

To provide independent confirmatory evidence for the presence of interruption sequences in the 27S nRNA, we have compared the nucleotide sequences of the 13S mRNA and 27S nRNA in the area of the *V-C* junction (Fig. 5). To facilitate this comparison, cDNA was made complementary only to the C_κ region by using T_2 - G_3 -T primer in a reverse transcription using limiting concentrations of dCTP (0.05 μ M). The cDNA which

results from this reaction is mainly 100–200 bases in length. As the T_2 - G_3 -T initiates just within the *C* region^{25–27}, material less than 298 residues in length is complementary only to C_κ sequences. Thus, when the C_κ cDNA is hybridised to the C_κ sequences of either mRNA or nRNA and re-extended using the hybrid RNA as a new template, the sequence of the extended cDNA will be governed by the sequence of the new template. By incorporating the dideoxynucleotides as chain terminators in the re-extension transcription³⁰, we can generate a series of sequence-specific stopping points which can be visualised by fractionation of the resultant cDNA on acrylamide gels³¹. Figure 5 shows this sequence comparison using mRNA or 27S nRNA as template and dideoxy-TTP as the chain terminator. Clearly, the cDNA has increased in size as a result of annealing and re-extension on the RNAs (slots 2 and 3) compared to the starting cDNA population (slot 1). By comparison with the sequence of the mouse C_κ region²⁷, we can approximately position the bands on the gel with respect to amino acid residues in the protein. For reference in Fig. 5 an arrow has been marked at the T residue present in the codon corresponding to amino acid 110 (Asp) which is close to the *V-C* junction as defined by amino acid sequence data. Therefore, the sequence approximately up to this residue is C_κ -region sequence. Clearly, the cDNA band patterns resulting from extension on the mRNA and on the 27S nuclear RNA are identical up to around this residue, demonstrating that the C_κ sequences of these RNA species are identical. In addition, this result shows the lack of interruptions in the C_κ sequence of the nuclear RNA (at least

Fig. 4 The pattern of S_1 nuclease protection of L-chain cDNA by resedimented nRNA pools. Pools a_1 , b_1 and $a_2 + b_2$ (from Fig. 3) were ethanol precipitated, hybridised with *V + C* cDNA, digested with S_1 nuclease and fractionated on a polyacrylamide gel to visualise the protected cDNA fractions as in Fig. 2. The sizes of the various cDNA bands were calibrated using denatured nick-translated *Hae*III-digested Φ X174 (slot 4) and a 362-base fragment of *Xenopus* 5S DNA (slot 5). Mixed with the latter fragment in slot 5 was a sample of the *V + C* cDNA (700 bases). The other slots show the S_1 protection pattern of pool a_1 (slot 1), pool b_1 (slot 2) and pools $a_2 + b_2$ (slot 3). Slots 1 plus 2 and 3 to 5 have been exposed for different times for maximum display.

between the equivalent of amino acids 110 and 205). However, the cDNA band patterns obtained using the 27S nRNA clearly begins to differ from that obtained with the cytoplasmic mRNA at a position which approximates to the V-C junction. This difference of band pattern therefore reflects a difference of base sequence of the two RNA species after this area of the sequence. Thus, the result confirms unequivocally the presence of a sequence in the 27S nRNA which is absent from the mRNA. This interruption sequence is presumably adjacent to the C_κ region, which means that the MOPC 21 V region is not adjacent to the C_κ in this 27S nRNA. Localisation of the precise point of sequence divergence in the two RNA species must await actual sequence data on the 27S nRNA itself.

Two steps in the integration of V and C genes

The results described indicate that two RNA populations can be isolated from the same nuclei of MOPC 21 cells; one of these nRNA species exhibits a sequence arrangement of V and C genes similar to that in mRNA (that is, continuous V and C regions), and the other nRNA (27S) exhibits the interrupted arrangement of V and C regions which occurs in the DNA itself. The most likely scheme of events would, therefore, seem to be that the 27S species is a precursor of the 13S nRNA and that the final removal of interruptions from V and C regions occurs in processing events of nRNA. Evidence in favour of the 27S molecule as a precursor of L-chain mRNA comes from pulse-labelling experiments²⁸. In these experiments a shortlived 40S nRNA was found to be the initial transcript of the *Ig* gene in MOPC 21 cells. This 40S molecule was shown to be the precursor of a 24S molecule, and in turn the 24S RNA was found to be the precursor of the 13S nRNA. This 24S nRNA species is presumably equivalent to the 27S nRNA molecule discussed here and thus, this 27S molecule would be the precursor of the 13S nRNA and cytoplasmic mRNA.

It is impossible to say whether V and C regions are on the same molecule or whether the 27S fraction contains one molecule with the C region and another molecule with the V region. One piece of indirect evidence suggests that the V and C regions are on the same molecule. This evidence comes from experiments with myeloma/spleen cell hybrids³² in which, for example, there is no mixing of the C_H sequences and the V_H sequences, from the two parental cells, in the hybrid line. Final resolution of this point however, must await further characterisation of the 27S nRNA.

Integration of the V and C genes has commonly been supposed to occur at the level of DNA. We now know that this is only partially true and are able to present a two-step model for integration of V and C_κ genes (Fig. 6). The first step of the integration seems to be at the level of DNA. The inherited germ-line DNA carries separate V and C_κ genes which, by a process of DNA rearrangement, seem to be brought closer together in the DNA of the antibody-producing cell^{2,3}. An interruption remains in the DNA at or near the V and C_κ junction even after this rearrangement³. These events are the classical 'integration' events as defined by genetics. This relocation of the *Ig* genes would be the mechanism by which a cell becomes committed to produce a particular V gene and may also be responsible for activating the *Ig* gene itself. The second step of the integration process occurs after transcription of the gene and involves elimination of the interruption sequences of V and C genes in the nuclear RNA. The initial transcript(s) of the active *Ig* gene includes the V region, the interruption sequence and the C region. The discontinuous V and C_κ regions of the precursor nRNA(s) are presumably joined by a looping out of the intervening sequence followed by ligation of V and C_κ regions. This process gives rise to the 13S nRNA and in turn to active cytoplasmic mRNA where the V and C_κ regions are continuous.

In this discussion, we have specifically referred to the splicing of the interruption at or near the V-C junction by nRNA processing. This processing scheme will also probably be

Fig. 5 Comparison of the sequences near the V-C junction of 13S mRNA and 27S nRNA. ^{32} P-cDNA was prepared with reverse transcriptase using MOPC 21 κ mRNA as template and T₂-G₃-T as primer^{26,27}, with 0.05 μ M dCTP and 10 μ M dGTP, dTTP plus 4 μ M ^{32} P-dATP. After incubation for 30 min at 37 °C the reaction mix was boiled for 5 min with 0.5 M NaOH neutralised with 1 M NaH₂PO₄, and the cDNA purified by chromatography on Sephadex G-100. The cDNA was annealed with either κ mRNA or 27S nRNA in 100 mM NaCl at 60 °C for 1 h. The cDNA was re-extended in the RNA:cDNA hybrid with reverse transcriptase in fresh reactions containing 100 μ M dATP, dCTP, dTTP and dGTP plus 10 μ M dideoxy-TTP³⁰ for 30 min at 37 °C and fractionated on 8% polyacrylamide gel in 8 M urea³¹. Slot 1, ^{32} P- Φ X174 digested with *Hae*III; slot 2, ^{32} P-cDNA starting material (not re-extended); slot 3, ^{32} P-cDNA re-extended on 13S messenger RNA; slot 4, ^{32} P-cDNA re-extended on 27S nuclear RNA. The arrows represent the position of a T residue in the codon equivalent to amino acid residue 110.

responsible for removing other interruptions which may occur in *Ig* genes. It has recently been shown, for example, that a germ-line V_{λ} gene possesses a short interruption in its linear sequence³³, and it is possible that V_{λ} genes possess insertions, as we were unable to detect a complete *V*-region size fragment in S_1 nuclease protection experiments with either MOPC 21 DNA³ or the 27S nRNA described here. It is also likely that nuclear RNA processing will be a general process for removal of the interruptions which have been found in other eukaryotic genes and in viral systems. Indeed, it has recently been shown that a globin nuclear RNA precursor possesses an interruption sequence which is absent from the mRNA³⁴.

Fig. 6 Two-step model for integration of variable and constant region genes. Step 1, the inherited germ-line DNA carries separate *V* and *C* genes. These genes are brought closer together in the antibody-producing cell, but an interruption at or near the *V*-*C* junction remains in this DNA. This rearrangement or translocation of DNA is the classical 'integration' event and it is the event which allows the individual antibody-producing cell to become committed to a *V* gene. Step 2, transcription of the activated gene occurs to produce a nuclear RNA precursor which encompasses the *V* and *C* regions plus the interruption sequence(s). Functional integration of the *V* and *C* regions occurs during the processing of the precursor molecule, presumably by a looping out of the interruption sequence(s) followed by ligation of *V* and *C* regions. The sequence arrangement of the mRNA is thus achieved and from this the Ig polypeptide is made. It is predicted that any further insertions (such as may exist in the *V* region) will also be eliminated by nuclear RNA splicing.

Hypothetical scheme for Ig heavy-chain gene expression

The joining of *V* and *C* genes in the nuclear RNA may well explain some of the problematical features of Ig heavy(H)-chain gene expression. During the immune response there is a shift from IgM to IgG production, which seems to be the result of a switch of H-chain class within single clones^{35,36}. It has been shown that a single myeloma patient produces an identical V_H sequence in IgM and IgG^{37,38}, and other studies have shown that single cells apparently produce identical V_H regions in association with C_{μ} and C_{δ} (refs 39, 40). Thus, a cell becomes committed to a heavy-chain *V* gene and this same *V* gene can, at various times, associate with C_{μ} , C_{γ} and C_{δ} . It is also possible that a further association with C_{α} can occur, as an identical V_H sequence has been found in a myeloma patient producing IgG and IgA⁴¹. There does not seem to be a recommitment of the antibody specificity of a given cell, and previous models have envisaged either successional insertion of a V_H gene to the different C_H genes³⁷ or simultaneous insertion of copies of the V_H gene with the C_H genes⁴². A further model may now be proposed in which the processing of heterogeneous nuclear RNA is the site of association of the 'committed' V_H gene with the various C_H genes (Fig. 7). Thus, a single V_H gene is selected

from the V_H -gene pool and DNA rearrangement occurs to bring the V_H gene to the proximity of the C_H -gene array. Primary transcription of the active H-chain gene unit may now occur to produce a giant nuclear RNA precursor containing the V_H region and the various C_H -gene classes. The cell can now produce from one nuclear RNA precursor species the same V_H region associated with any of the C_H classes by processes of looping out intervening sequences, ligation of the V_H and C_H regions, followed by degradation of the unwanted RNA. A single cell, therefore, using such an nRNA precursor, could produce simultaneously or sequentially one, two or three mRNA species containing the same V_H sequence with the different C_H sequences. As shown in Fig. 7, this is a minimal model involving only the C_{μ} , C_{δ} and C_{γ} genes: there are some data suggesting the involvement of C_{α} but little evidence for involvement of C_{ϵ} . The minimal model can, however, easily be adapted to include these C_H genes if necessary by simply hypothesising their inclusion in the giant nRNA molecule. A general

Fig. 7 Hypothetical scheme for expression of a single heavy-chain V_H gene with multiple C_H genes. (1) The V_H -gene pool is depicted as a set of genes linked to the C_H -gene array. The order of the C_H genes is hypothetical and for simplification no subclasses of the C_H genes are shown. A single V_H gene (V_H^x) is selected for expression and DNA rearrangement occurs to bring the V_H^x and C_H genes closer together. A *V*-*C* interruption sequence may or may not exist between V_H^x and C_H (depicted as S). This process of rearrangement will commit the cell to a V_H gene and may also activate the H-chain transcription unit. (2) Transcription of the H-chain unit produces a giant nRNA precursor encompassing the V_H^x -gene *V*-*C* interruption sequence (if this occurs) and the C_H genes. (3) Intranuclear processing of this giant nRNA molecule can give rise to any combination of V_H^x and C_H in mRNA. Thus, (3a) $V_H^x C_{\mu}$ mRNA can be generated by looping out of the *V*-*C* interruption sequence, ligation of V_H^x and C_{μ} followed by degradation of the remaining RNA; (3b) $V_H^x C_{\delta}$ mRNA by looping out sequence 'S' plus the C_{μ} sequence followed by ligation of V_H^x with C_{δ} ; (3c) $V_H^x C_{\gamma}$ mRNA can be made from the same nRNA precursor by analogous processing events. A single cell can therefore simultaneously make one, two or three mRNA species with the same V_H gene and different C_H genes. 'Spacer' sequences must occur between the C_H genes to allow specificity of processing: these putative sequences would, of course, be eliminated by the nRNA processing. The model shown is a minimal model, as it excludes C_{α} and C_{ϵ} . It is possible that C_{α} (and C_{ϵ}) could also be involved in the pathway, in which case they can readily be accommodated by adapting the hypothetical giant nRNA precursor to include one or both of these C_H genes.

feature of the model is that it makes very clear predictions which can be tested experimentally.

In the way described, a single event (that is, the event responsible for V_H -gene commitment) is required for both activation of the heavy-chain gene transcriptions and multiple expression of the same V_H gene with any of the C_H genes at the level of mRNA. How is the required specificity of RNA joining likely to be achieved with a 'multicistronic' nRNA precursor of this type? Presumably, this joining is mediated through an enzyme or enzymes which can be either specific for the different genes or nonspecific, relying on RNA folding properties to achieve specificity. If specific enzymes are used it means that a large array of different species must exist, whereas nonspecific enzymes require only intrinsic properties of the gene sequence itself for correct joining. There are as yet no clues about the processes of RNA joining but doubtless, *in vitro* systems will be useful in exploring this aspect of RNA joining.

I thank A. Forster for technical assistance, J. R. Miller for *Xenopus* 5S DNA, Dr J. W. Beard for reverse transcriptase, and Dr C. Milstein for discussions.

letters to nature

X-ray emission from the companion to V861Sco

THE Copernicus satellite has observed V861Sco (Hr6283, Spectrum; $B0.5$ Ia, $V = 6.2$, $B - V = +0.28$, $U - V = -0.72$) as part of a programme devoted to the study of mass transfer in binary star systems. The programme described here uses the Princeton UV telescope¹ to make detailed measurements of absorption lines in the UV spectra of such stars. X-ray measurements are made simultaneously with a co-aligned proportional counter².

Significant signals from the X-ray detector were obtained during the first observation from 24 to 26 April 1978. The flux recorded, averaged over 1.2-h intervals, is shown in Fig. 1. At the end of the observation on 26 April a significant fall in intensity was observed. The hypothesis that this fall in intensity was caused by an eclipse of the X-ray source, was tested by a second observation which began on 27 May 1978. Results of this second observation are shown in Fig. 2. The flux was observed to decline at a time consistent with the known 7.8-d period⁷ of V861Sco. The low flux state lasts at least 1.3 d and the decline to this level occurred over a 0.7-d period.

There is no evidence of regular modulation (as is common with neutron star sources) greater than 15% peak to mean flux in the range 3-40 min.

The X-ray spectrum, observed when the signal was at maximum intensity, is shown in Fig. 3. Appreciable photoelectric absorption is present. The column density is equivalent to

$(4 \pm 1) \times 10^{23}$ H atoms assuming normal cosmic abundances and a thermal spectrum with a temperature equivalent to 11 ± 4 keV. The interstellar column of both atomic and molecular hydrogen to this region is $(2.3 \pm 1.0) \times 10^{21}$ atoms³. There is, therefore, considerable photoelectric absorption intrinsic to the source.

The Princeton guidance system maintains the pointing accuracy of both instruments to better than 0.1 arc s throughout the observing period. However, the beam width of the X-ray detector is 2.5° by 3.5° , full width at half maximum (FWHM), so the field has been examined for catalogued sources. No known sources were within the field with the exception of 4U1702-42 which was 2.8° from the centre for the V861Sco observations. 4U1702-42 is catalogued⁴ at 30 Uhuru flux units and would only contribute 3% or less than 1 OAO count in 62.9 s (the Crab nebula gives 375 OAO counts in this integration period). The signals observed by the Copernicus instrument thus indicate the presence of a new source which has been designated OAO 1653-40 (ref. 5).

The variable star V861Sco was shown by Walker to be a spectroscopic binary with a 7.8-d period and a mass function of 0.487 solar masses ($M_\odot$). A collapsed object was suggested as a possibility for the unseen companion⁷. Although Walker assumed the primary to have a mass 10 times that of the Sun ($10 M_\odot$), more reasonable estimates would be 20-30 $M_\odot$ implying a mass of 7-11 $M_\odot$ for the secondary, the actual value depending on the inclination of the system. This range is above the limit for a neutron star indicating that the compact secondary is a black hole.

Fig. 1 First observation of V861Sco. The significant drop in the X-ray signal can be seen at the end of the observation. Times of observation of other target stars (used for background determination) are also indicated.

The X-ray observations support the identification of OAO 1653-40 with V861Sco. The two reductions in signal are separated by exactly four cycles of the binary star orbit and this is the strongest evidence for the suggested identification. A new orbital ephemeris is required to relate the phasing of the X-ray and optical data. UV observations obtained in three spectral regions ($\lambda\lambda$ 1110-1130, 1167-1185 and 1230-1247) during the X-ray eclipses indicate a stellar spectrum similar to that of κ Ori. Broad, strong, violet-displaced (by about -700 to -800 km s $^{-1}$) absorption components are seen in C III λ 1176, N V λ 1238 and λ 1242. Weak Nv emission may also be present. These observations are, however, insufficient to relate the phases of the X-ray source and V861Sco.

The observed X-ray luminosity (3.8-8.8 keV and assuming a Crab-like spectrum) is given by $4 \times 10^{34} R^2$ erg s $^{-1}$ where R is the distance to the source in kpc. V861Sco is a member of the association Sco OB1 (ref. 8) and using the distance (1.95 kpc) to this cluster we obtain an X-ray luminosity of 1.5×10^{35} erg s $^{-1}$. The emission outside this energy band and electron scattering near the source increase the estimate of luminosity, possibly by several orders of magnitude.

When the X-ray source is in eclipse there is a significant residual signal at approximately 0.25 the non-eclipsed value.

Fig. 2 Second observation of V861Sco in which the expected eclipse is observed after four cycles of the binary star had passed since the first observation.

Further observations are needed to clarify the nature of this; for example, it may be a contaminating point source or arise from a possible supernova remnant in this association⁹.

The observed properties of OAO 1653-40 are so similar to those described for 4U1702-42 (ref. 4), that one might question whether the position of the latter is in error. Preliminary analysis of more recent data, obtained in July 1978, indicates that the intensity of the X-ray source has reduced considerably, implying that the source is transient within the sensitivity limits

Fig. 3 The observed X-ray spectrum when the signal is at maximum intensity. A thermal spectrum has been fitted to the data but other spectral forms are not precluded. Significant photoelectric absorption is evident. Solid curve, thermal spectrum:

$$P(E) = \frac{(0.120 \pm 0.005)}{E} \exp\left(\frac{-E}{11 \pm 4}\right) \exp\left[(4 \pm 1) \times 10^{23} \sigma_{\text{BG}}\right]$$

(σ_{BG} are the Brown and Gould¹⁰ cross-sections for interstellar absorption).

of the Copernicus detector. If the association of the X-ray source with V861 is correct then either the known variable mass flow⁶ has caused further obscuration or has reduced accretion which has diminished the X-ray output.

We thank N. E. White for providing the constraints to regular pulsations.

Note added in proof: Clarification of the optical ephemeris and additional X-ray measurements suggest the observed decreases in flux are caused by the 'eclipse' of the X-ray source by a dense gas stream in the system. A true eclipse of the X-ray source by the primary star has recently been observed with Copernicus in further observations.

COS B observation of high-energy γ radiation from 3C273

THE discovery of a high-energy γ -ray source at $\alpha(1950)=12^{\text{h}} 29^{\text{m}} \pm 6^{\text{m}}$, $\delta(1950)=+3^{\circ} \pm 1.5^{\circ}$ is reported here. Arguments are given for the identification with 3C273. If this identification is correct, the γ -ray luminosity of 3C273 in the energy range 50–500 MeV is $2 \times 10^{46} \text{ erg s}^{-1}$ for $H_0=60 \text{ km s}^{-1} \text{ Mpc}^{-1}$.

The majority of the reported γ -ray sources are galactic, as can be clearly established from their latitude distribution¹. The lack of unambiguous identification (with the exception of CG185–5 with PSR0531+21 and of CG263–2 with PSR0833–45) leaves a wide range of speculations as to the classification of the sources and to the nature of the emission mechanisms. The outstanding signature of these sources is the fact that their γ -ray luminosity ($>50 \text{ MeV}$) exceeds at least the radio and X-ray luminosities. Besides the continuing search for galactic γ -ray sources, some observations of the ESA γ -ray observatory COS B have been devoted to extragalactic targets². The region of the sky centred on $\alpha=12^{\text{h}} 24^{\text{m}}$, $\delta=+7^{\circ}$ with an effective field of view of about 20° radius was observed from 24 May to 24 June 1976. This observation was particularly aimed at a sensitive search for high-energy γ -ray emission from M87 and 3C273.

The data have been analysed using a cross-correlation method: the frequency distribution of arrival directions of γ rays was correlated with the distribution expected for a point source as determined by calibration and confirmed by flight data on the strong source PSR0833–45 (ref. 2). The resulting correlation map follows the distribution expected for random data, apart from one clear maximum, which has a probability of 10^{-5} of being caused by random fluctuations at any position in the map. This excess follows the distribution expected for a point source located within a 90% probability error box defined by $\alpha(1950)=12^{\text{h}} 29^{\text{m}} \pm 6^{\text{m}}$, $\delta(1950)=+3^{\circ} \pm 1.5^{\circ}$. Spectral information was obtained by analysing the data in two energy ranges. In each case a significant excess within the same error box was found. The derived characteristics of this source (designated CG291+65) are summarised in Table 1. The errors quoted include the estimated systematic errors.

Table 1 Characteristics of CG291+65

Position	$\alpha(1950)=12^{\text{h}} 29^{\text{m}} \pm 6^{\text{m}}$	$\delta(1950)=+3^{\circ} \pm 1.5^{\circ}$
Intensity	50–150 MeV	$(1.2 \pm 0.4) \times 10^{-6} \text{ photons cm}^{-2} \text{ s}^{-1}$
	150–500 MeV	$(0.3 \pm 0.1) \times 10^{-6} \text{ photons cm}^{-2} \text{ s}^{-1}$
Energy flux	50–500 MeV	$3 \times 10^{-10} \text{ erg cm}^{-2} \text{ s}^{-1}$

Of the two specific targets of this observation, M87 is about 8° outside the error box, and is therefore clearly not the source of the detected γ rays. On the other hand, 3C273 lies well within the error box. Despite the large size of this error box, the following compelling arguments for an identification with 3C273, the second nearest of the powerful QSOs ($z=0.158$), can be made. The probability of finding a known high-galactic-latitude X-ray source by chance within a $3^{\circ} \times 3^{\circ}$ error box is about 2%. However, the X-ray source 4U1226+02 ($\equiv 2A1225+022$) lies within the error box of CG291+65. This X-ray source has been positively identified with 3C273 (refs 3, 4). Also, it is stressed that the probability of finding a chance coincidence of the error box with a specific object, that is 3C273, is $<1\%$.

If this identification is correct the observed intensities at γ -ray energies can be compared with those at other wavelengths, as shown by the spectrum in Fig. 1. This shows that a major portion of the energy radiated by 3C273 is in the form of γ rays. Its γ -ray luminosity in the range 50–500 MeV is $\sim 2 \times 10^{46} \text{ erg s}^{-1}$ for $H_0=60 \text{ km s}^{-1} \text{ Mpc}^{-1}$.

Fig. 1 Spectrum of 3C273 from radio to γ -ray energies. The intensity scale is given in units of power per decade. The radio (R), optical (O) and X-ray (X) data are those given in a compilation by Apparaio *et al.*⁵. The IR data are from Rieke and Low⁶.

This has important consequences for the understanding of QSOs and warrants extensive efforts to further strengthen the identification. Repeated observations of 3C273 may yield signs of time variability, similar to those clearly established at other wavelengths, with amplitudes which tend to increase with increasing energy⁵. A second observation by COS B is planned for June/July 1978. Somewhat less directly, the identification could be strengthened by an extensive search for γ -ray emission of other QSOs. In this context, note that the newly discovered and nearest QSO, associated with 2S0241+622, lies within the error box of CG135+1 (ref. 5).

The intriguing fact that all γ -ray sources detected by COS B, including pulsars, unidentified galactic sources and possibly extragalactic sources, have a peak luminosity at γ -ray energies, may indicate some similarity in the emission process, or may reflect a selection caused by the limited dynamic range of detected γ -ray fluxes.

Infrared observations of the most luminous quasar

The QSO Q 0420–388 is one of many discovered by Osmer and Smith in their objective prism survey of the southern sky, and one of ~ 10 now known with $z > 3$. Its brightness and large redshift indicate a luminosity at rest wavelength $1,475 \text{ Å}$ somewhat larger than any other measured. The source is particularly noteworthy because of the steepness of its observed visual spectrum over the range $3,600\text{--}6,800 \text{ Å}$, where $F_v \sim$

$\nu^{-2.1}$; this suggests that appreciably more power might be radiated in the infrared (IR). The near IR photometric observations reported here of Q 0420-388 ($z = 3.12$) show that it is 13.5 ± 0.2 mag at $2.2 \mu\text{m}$. This observation and the optical observations of Osmer and Smith¹ indicate a bolometric luminosity $\geq 5 \times 10^{14} L_{\odot}$ for $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and $q_0 = 0.1$ confirming Q 0420-388 as the most luminous quasar for cosmologies with small q_0 .

Table 1 gives accurate positions for the quasar and a nearby star, as measured from the ESO B survey plates. These positions are derived from those of the five nearest SAO stars (194936, 194939, 194974, 194977, 194979) including the effects of the proper motions of these stars.

Using the 1.5 m telescope at CTIO and the InSb photometer of the Center for Astrophysics, we observed Q 0420-388 at $2.2 \mu\text{m}$ ($1.36 \times 10^{14} \text{ Hz}$) on 27 July 1977 and 30 July 1977, obtaining consistent results whose weighted mean is $K = 13.5 \pm 0.2$ mag, corresponding to a $2.2 \mu\text{m}$ flux of $2.5 \pm 0.5 \text{ mJy}$. We used a $35''$ diameter beam, and a beam separation of $96''$ in declination. The star in Table 1 is the only one visible on the Whiteoak extension of the Red Palomar Sky Survey that might interfere with our measurement of the quasar. This star is $34''$ SE, well outside our beam, and a separate measurement of its brightness gave $K = 12.9 \pm 0.7$ mag; the star is too faint and too far separated for scattered light from it to affect our measurement of the QSO.

The flux distribution $\lambda F_{\lambda} = \nu F_{\nu}$ is given in Fig. 1. Osmer and Smith¹ give a flux of 0.6 mJy at $6,077 \text{ \AA}$ (rest wavelength $1,475 \text{ \AA}$). Combined with our result, this gives $F_{\nu} \sim \nu^{-1.1 \pm 0.2}$ for the range $0.6-2.2 \mu\text{m}$. This spectral index is consistent with the range of values quoted by Osmer and Smith for the $0.36-0.68 \mu\text{m}$ region, and it may be that the spectral index of the quasar is -1.1 ± 0.2 over the entire $0.36-2.2 \mu\text{m}$ range. The high galactic latitude of the source, $|b| \sim 45^\circ$, suggests that the galactic extinction is low. Thus, a change in the apparent spectral index of the source would reflect its intrinsic behaviour. Q 0420-388 is not listed in the Parkes catalogue², so its flux at $2,700 \text{ MHz}$ cannot be more than 220 mJy . This result and our $2.2 \mu\text{m}$ measurement indicate that the spectral index between the radio and near IR is > -0.4 . From their observations of high redshift QSOs in the Molonglo survey, Baldwin *et al.*³ infer that there is a preponderance of such flat spectrum sources among high z objects.

We have estimated the bolometric flux using $\nu F_{\nu} \sim \nu^{-1}$ for $\lambda < 6,077 \text{ \AA}$, $\nu F_{\nu} \sim \nu^{-0.1}$ for $0.61 \mu\text{m} < \lambda < 2.2 \mu\text{m}$, and $\nu F_{\nu} \sim \nu$

Table 1 Precise positions

Object	$\alpha(1950)$				$\delta(1950)$			
	h	m	s	s	°	'	"	"
Q 0420-388	04	20	30.07	± 0.05	-38	51	50.4	± 0.6
Star SE of QSO	04	20	31.95	± 0.05	-38	52	16.9	± 0.6

for $\lambda < 2.2 \mu\text{m}$. This gives $F_{\text{bol}} = (1.05 \pm 0.2) \times 10^{-14} \text{ W m}^{-2}$, or $L = 5 \times 10^{14} L_{\odot}$ if $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and $q_0 = 0.1$. For $q_0 = 0$ or $q_0 = 1$ the values for L would be $7 \times 10^{14} L_{\odot}$ and $1 \times 10^{14} L_{\odot}$ respectively. More extensive IR observations would test the suitability of the spectral indices used above, and provide a better estimate of the luminosity. Our estimate will be too large if the broad bandpass $2.2 \mu\text{m}$ ($\Delta\lambda = 0.4 \mu\text{m}$) observation is strongly affected by H β and OIII, which are redshifted to just inside the bandpass. On the other hand, our luminosity estimate will be too small if the spectral distribution of Q 0420-388 continues its rise into the IR. If the spectrum rises as $\nu^{-1.1}$ out to $10 \mu\text{m}$, it will be 4 mJy (12.2 mag) at $3.5 \mu\text{m}$ and 13 mJy (8.7 mag) at $10 \mu\text{m}$, and the luminosity will be $8 \times 10^{14} L_{\odot}$. If Q 0420-388 rises into the IR as rapidly as 3C232, it will be $\sim 20 \text{ mJy}$ at $10 \mu\text{m}$ and the minimum total luminosity will be $13 \times 10^{14} L_{\odot}$. Detections at these low flux levels should be

Fig. 1 Luminosity of Q 0420-388 and comparison quasi-stellar objects. The luminosity is expressed in solar units; the frequency is the rest frequency. The data points and connecting lines are drawn for $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and $q_0 = 0.1$. The edges of the shaded zones indicate the maximum luminosity, when $q_0 = 0$, and the luminosity when $q_0 = 0.5$. For Q 0420-388 the $\lambda_{\text{rest}} = 1,475 \text{ \AA}$ point is from Osmer and Smith¹; the datum at $\lambda_{\text{rest}} = 0.53 \mu\text{m}$ is from this paper. The dashed lines show the spectral behaviour assumed in calculating the luminosity. For the comparison quasars, Δ are UVB observations from the compilation of Smith-Haenni⁷, and $\blacksquare$ are from Rieke and Low⁵. The $\lambda_{\text{rest}} = 1.41 \mu\text{m}$ point for QSO 3C334 is a $2.2 \mu\text{m}$ observation given by Oke *et al.*⁶.

possible with long integrations on large, low-background Southern Hemisphere telescopes.

The obvious sources for comparison with Q 0420-388 do have spectra that rise into the IR. The most luminous galaxy, Markarian 231, has a bolometric luminosity of $\sim 4 \times 10^{12} L_{\odot}$, and the most famous quasar, 3C273, has a bolometric luminosity of $\leq 3 \times 10^{13} L_{\odot}$ (ref. 4). The most luminous quasar observed by Rieke and Low⁵, 3C232, can be (generously) estimated to have a bolometric luminosity of $\sim 2 \times 10^{14} L_{\odot}$, assuming that at IR wavelengths longer than $10 \mu\text{m}$ it is similar to 3C273.

The luminosity of Q 0420-388 seems to be temporally sustained. From spectrophotometric and near IR studies of 28 QSOs, Oke *et al.*⁶ argued that a steep rise into the IR ($\alpha < -1.5$) might be a necessary but not sufficient condition for rapid variability of a QSO, and that if such variation occurred, the entire UV-near IR spectrum rose or fell. The visible-IR spectral index of Q 0420-388, $\alpha = -1.1 \pm 0.2$, is shallower than the $\alpha < -1.5$ cut-on value. Moreover, the persistence of Q 0420-388 on the Whiteoak extension, on the ESO B plate series, and on the discovery plates of Osmer and Smith suggests its relative constancy. A most important finding is that the quasar is evident on seven plates in the Harvard collection (ranging back to 1936) and there is no conclusive evidence for its having varied by more than $\sim 1/2 \text{ mag}$. Thus, the luminosity may be constant, at least for time scales of several years. Additional IR and optical observations to establish the temporal behaviour of Q 0420-388 are clearly important for defining the energy requirements of the source.

We thank several colleagues for helpful comments, in particular Ms Lola Chaisson for studies of the Harvard plates, under NSF grant AST 76-00537. This paper uses our observations made as guest investigators at Cerro Tololo Interamerican Observatory, which is operated under contract to the NSF.

Low energy neutrino elastic scattering and supernova explosions

COLGATE AND WHITE¹ have proposed that neutrinos could transport energy outwards during the gravitational collapse of a star, thus initiating a supernova explosion. Detailed calculations by Wilson² seemed to rule out this possibility, but Freedman³ pointed out in the context of unified gauge theories of weak and electromagnetic interactions that there could be both a large neutrino-neutron elastic scattering cross section and a very large coherent neutrino-heavy nucleus cross section. Wilson⁴ has recently recalculated the collapse of an iron core formed at the end of a stellar evolution from massive stars and shown that the calculations do simulate an explosion, and that a stronger explosion results from smaller coherent scattering off heavy nuclei. This surprising result arises because a smaller cross section allows more neutrinos to escape, lowering the pressure and thereby letting the neutron core reach a higher density before the outward shock wave is formed. We have calculated neutrino-nucleon and neutrino-heavy nucleus neutral current cross sections in weak SU(2)×U(1) and compared with those of the standard unified theory. Important differences are found which could make simulated supernova explosions easier to obtain. Possible experiments to test the two theories are outlined here.

The theory of neutral weak currents which agrees with all high energy neutrino experiments is the renormalisable and unified spontaneously broken gauge theory based on the group SU(2)×U(1) (ref. 5). This provided the basis for the recent calculations by Wilson⁴ and others^{6,7}. We have suggested previously an alternative theory⁸ based on the same group which we call weak SU(2)×U(1) (as it does not involve the photon) and which is very hard to distinguish from the Weinberg model⁵ in high energy neutrino scattering. Nevertheless, there are marked differences which should have a significant effect on the supernova calculations. In particular, in weak SU(2)×U(1) there is essentially no coherent scattering of neutrinos off heavy nuclei whereas the neutrino-neutron cross section is changed relatively little.

We shall now briefly derive these results, using the notation in ref. 8. In unified SU(2)×U(1), the neutral weak hadronic current is

$$J_\mu = A_\mu^3 + (1 - 2 \sin^2 \theta_w) V_\mu^3 - 2 \sin^2 \theta_w V_\mu^S \quad (1)$$

This gives the matrix elements for neutrino-nucleon scattering

at small momentum transfer

$$\langle n | J_\mu | n \rangle = -\bar{u}_n (\gamma_\mu + g_A^3 \gamma_\mu \gamma_5) u_n \quad (2a)$$

$$\langle p | J_\mu | p \rangle = \bar{u}_p [(1 - 4 \sin^2 \theta_w) \gamma_\mu + g_A^3 \gamma_\mu \gamma_5] u_p \quad (2b)$$

where $g_A^3 = -1.25$ is the isovector axial renormalisation factor. Experimentally $\sin^2 \theta_w \approx \frac{1}{4}$ and so equation (2b) predicts that the proton neutral current is nearly pure axial. For $\sin^2 \theta_w = \frac{1}{4}$ the nonrelativistic cross sections in the Weinberg model are then

$$\sigma(\nu n \rightarrow \nu n) = G^2 p^2 (1 + 3(g_A^3)^2) / 4\pi \quad (3a)$$

$$\sigma(\nu p \rightarrow \nu p) = 3G^2 p^2 (g_A^3)^2 / 4\pi \quad (3b)$$

where p is the neutrino momentum. (In refs 6 and 7 it was assumed that $g_A^3 = -1$, thus reducing the cross section (3a) by about 30%.)

For neutrino scattering off a nucleus with Z protons and N neutrons equation (1) gives

$$\begin{aligned} \langle (Z, N) | J_\mu | (Z, N) \rangle \\ = (1 - 4 \sin^2 \theta_w) Z - N + \text{noncoherent terms} \end{aligned} \quad (4)$$

This shows that the neutrino-nucleus cross section in the Weinberg model should have a large coherent part which is proportional to N^2 for $\sin^2 \theta_w = \frac{1}{4}$. Note that this coherent contribution in this model happens to be just the quantity Q_w that should have been measured as a parity violation in atomic bismuth⁹. It was the failure to observe this effect which led to alternative versions of the weak current.

In weak SU(2)×U(1) the vector and axial current are interchanged. Thus instead of equation (1)

$$J_\mu = V_\mu^3 + (1 - 2 \sin^2 \theta_w) A_\mu^3 - 2 \sin^2 \theta_w A_\mu^S \quad (5)$$

There is now no vector isoscalar component (in Freedman's³ notation $a_0 = 0$) and so instead of equation (4)

$$\langle (Z, N) | J_\mu | (Z, N) \rangle = Z - N + \text{non-coherent terms} \quad (6)$$

Instead of equations (2a) and (2b) we have

$$\langle n | J_\mu | n \rangle = -\bar{u}_n [\gamma_\mu + g_A^3 \gamma_\mu \gamma_5 (1 - 2(1 - \lambda) \sin^2 \theta_w)] u_n \quad (7a)$$

$$\langle p | J_\mu | p \rangle = \bar{u}_p [\gamma_\mu + g_A^3 \gamma_\mu \gamma_5 (1 - 2(1 + \lambda) \sin^2 \theta_w)] u_p \quad (7b)$$

where $\lambda = g_A^S / g_A^3$ and g_A^S is the isoscalar axial renormalisation factor. If axial charge is a good quantum number $g_A^S = g_A^3$; on the other hand the quark model¹⁰ gives $g_A^S = \frac{2}{3} g_A^3$.

In terms of the ratios R_n and R_p of νn and νp cross sections in weak SU(2)×U(1) compared with those of unified SU(2)×U(1) above in the nonrelativistic limit, we have for $\sin^2 \theta_w = \frac{1}{4}$, and $\lambda = 1$

$$R_n = 1, \quad R_p = 0.21 \quad (8a)$$

and for $\sin^2 \theta_w = \frac{1}{4}$, $\lambda = \frac{2}{3}$

$$R_n = 0.7 \quad R_p = 0.25 \quad (8b)$$

(We take the quantity $\kappa = m_z \cos \theta_w / m_w$ of ref. 8 to be approximately given by $\kappa = 1$.) Therefore from equations (6)–(8), in weak SU(2)×U(1), neutrino-neutron cross sections are relatively unaffected while neutrino-proton cross sections are reduced by a factor of 4 or 5 on account of a pure axial current being replaced by a nearly pure vector current. There is very little coherent scattering and then only for heavy nuclei with $Z \neq N$. Spin $\frac{1}{2}$ nuclei with $Z = N \pm 1$ scatter neutrinos like protons or neutrons respectively.

These predictions should change the character of the supernova calculations. The most important effects of neutrinos in the calculations based on the Weinberg model come from neutrino-electron, neutrino-neutron and neutrino-heavy nucleus collisions^{6,7}. Energy is transferred most effectively in νe^- scattering and this is unchanged (neglecting the electron mass) in weak SU(2)×U(1) (ref. 8). The neutrino opacity in the neutron core is also relatively unchanged—the neutrino may

have a slightly longer mean free path in the neutron core—but what is drastically changed is the ability of the neutrino to scatter from heavy nuclei. There is now a much smaller opacity gradient between the neutron core and the $A > 1$ shell and therefore neutrinos will be able to escape through the $A > 1$ shell much faster: this could make explosions easier to obtain as higher densities in the core will be possible.

Finally, we should point out that it would be of great importance to decide experimentally between the two types of theory. Freedman³ suggested that an experiment on coherent neutrino-heavy nucleus scattering was possible by detecting the recoil nucleus, using neutrinos in the 100–200 MeV range from a 'meson factory'. Certainly a large coherent cross section would clearly discriminate in favour of the Weinberg theory or one with similar structure.

An alternative possibility is suggested by equation (8). It should be possible to measure $\nu p \rightarrow \nu p$ in the non-relativistic region at a reactor such as ILL, with a good high intensity point source of neutrinos. Recoil protons could be detected in either gas or liquid targets. If the experiment is performed it should be relatively easy to determine from the size of the cross section whether the amplitude is predominantly Gamow-Teller, as it is in the Weinberg theory for $\sin^2 \theta_w = \frac{1}{4}$, or Fermi and, therefore, 4–5 times smaller ($3(g_A^2)^2 = 4.7$) as it is in weak $SU(2) \times U(1)$.

Note added in proof. Weak $SU(2) \times U(1)$ predicts an asymmetry in polarised electron-deuteron scattering which is smaller than that observed in the recent SLAC experiment¹¹. On the other hand, the standard model is not in agreement with the Oxford and Washington experiments in bismuth vapour⁹. This confused situation makes it even more essential to measure the elastic neutrino-proton and neutrino-heavy nucleus cross sections at low energies, so that a clean determination of the weak hadronic neutral current can be made in this energy range.

Photofixation of carbon dioxide to formic acid *in vitro* using water as hydrogen source

THE function of photosynthesis *in vivo*, including subsequent dark reactions, is defined as the reduction of carbon dioxide coupled with oxidation of water to produce organic compounds. We now report the first example of a mimicking of the function of photosynthesis based on electron transport sensitisation^{1–4}. Although the product is not carbohydrate, we consider that the present reaction system consists of (1) electron transfer from the singlet excited state of an aromatic hydrocarbon such as pyrene(Py) or perylene(Pe) to an electron acceptor such as 1,4-dicyanobenzene(DCB) or 9,10-dicyanoanthracene(DCNA) in polar media; (2) successive electron transfer from the acceptor anion radical to carbon dioxide; (3) further reactions of carbon dioxide anion radical as demonstrated in

Table 1 Photochemical formation of formic acid sensitised by Pe-DCNA system

	Pe	DCNA	HCOOH	Yield (%)	
		(mg per 100 ml)		vs Pe	vs DCNA
I	6.6	15.9	3.2	270	100
II	6.2	17.0	~0	~0	~0
III	5.5	15.0	5.9	590	195
IV	1.6	4.3	1.3	450*	150*

A solution containing Pe and DCNA was irradiated (wavelength > 313 nm, runs I, II, IV, panchromatic irradiation, run III) by a 300 W high pressure Hg-arc lamp under CO_2 gas bubbling for 8 h (runs I, II, III) or 20 h (run IV). Formic acid in the reaction mixture was converted to the butyl ester and determined by gas-chromatography (polyethylene glycol 20 M 53°C). Runs I, III, IV, $\text{CH}_3\text{CN}:\text{H}_2\text{O} = 95:5$; run II, absolute CH_3CN .

* The turnover numbers for Pe and DCNA were calculated as 6.5 and 12.8, respectively, from the decomposed amounts of the sensitizers during photoirradiation determined spectroscopically.

electrolytic reduction of carbon dioxide to formic acid and oxalic acid^{5,6}.

The reaction process will then be expressed schematically as follows:

Photochemistry of carbon dioxide in condensed phase has been little studied, and the first example was the reductive coupling of aromatic hydrocarbon anion radicals with carbon dioxide to give dihydroaromatic carboxylic acids⁷. If the anion radical is sterically hindered so that the C-C bond formation with carbon dioxide is unfavourable, we expect electron transfer from the anion radical to carbon dioxide to occur. Although we cannot confirm the energetic feasibility of the electron transfer process, the available redox properties of relevant species suggest that it is a good possibility ($E_{1/2}(\text{CO}_2) = -2.15$ V (ref. 5), $E_{1/2}(\text{DCB}) = -2.00$ (ref. 8) ~ -2.48 V (ref. 9). There are no available directly comparable data for DCNA; however, the more negative value of $E(\text{A}/\text{A}^-)$ for DCNA (-0.82 V (ref. 10)) than that for DCB (-0.65 V (ref. 11)) would indicate the stronger reducing power of DCNA^- . Furthermore, the reductive fixation of CO_2 *in vivo* is coupled with the oxidation of NADPH which is apparently a weaker reducing agent than DCB^- ($E(\text{NADP}/\text{NADPH}) = -0.32$ V (ref. 12)). Thus, we carried out photoinduced electron transfer reactions in the atmosphere of carbon dioxide. The results are presented in Table 1 and 2.

The important results are summarised as follows. (1) An aqueous polar solvent is the essential requirement for the reaction. When dry acetonitrile was used, formic acid was scarcely produced (Table 1, run II, Table 2, run III). Furthermore, the yield of formic acid increased with the concentration of water (Table 2, runs, I, II). (2) As a matter of course, carbon dioxide is indispensable as the carbon source of formic acid (Table 2, run VI). (3) Qualitative confirmation of formic acid formation in other solvents such as aqueous methanol and aqueous DMF by means of spot tests¹³ indicated that these organic solvents did not play an essential part in reducing carbon dioxide. The role of organic solvents is assumed to dissolve D and A. (4) The D-A pair was indeed recycled, as evidenced by a yield of formic acid higher than 100% based on the initial concentration of D and A (Table 1, runs, I, III, IV). To recycle the electron transport system, another reducing species (X in the reaction scheme above) is required. We cannot yet draw any conclusion on the nature of X by which D is reproduced from D^+ , but probable candidates are OH^- , HCO_3^- and/or HCOOH . Iodometry of the reaction mixture (Py-DCB-TPA in $\text{CH}_3\text{CN}:\text{H}_2\text{O} = 5:1$, panchromatic irradiation for 8 h under a CO_2 pressure of

Table 2 Photochemical formation of formic acid sensitised by Py-DCB-TPA system

	[Py]	[DCB] ($\times 10^{-2}$ mol l $^{-1}$)	[TPA]	[HCOOH] ($\times 10^{-4}$ mol l $^{-1}$)
I	1.9	5.4	5.2	5.2
II	1.7	6.0	4.5	17
III	1.8	5.4	5.7	~0
IV	1.9	—	6.0	9.6
V	1.8	5.8	—	8.6
VI	1.9	5.6	5.4	0

A pressure tight pyrex vessel containing a solution of sensitisers was pressurised (4 kg cm $^{-2}$) with CO $_2$ (runs I-V) (or N $_2$) (run VI) and irradiated by a 300 W high pressure Hg-arc lamp for 8 h. Formic acid in the reaction mixture was esterified to the benzyl ester and determined gas-chromatographically. Runs I, VI, CH $_3$ CN:H $_2$ O = 95:5; runs II, IV, V, CH $_3$ CN:H $_2$ O = 5:1; run III, absolute CH $_3$ CN.

5 kg cm $^{-2}$) confirmed the formation of peroxide, suggesting that D $^+$ was reduced to D at least in part by the reaction, OH $^- \xrightarrow{e^-} 1/2$ H $_2$ O $_2$. (5) The turnover numbers of sensitiser (2X[HCOOH]/ Δ [sensitiser]) were determined to be 6.5 for DCNA and 12.8 for Pe (Table 1, run IV).

We have not yet determined the quantum yield of formic acid production, as the kinetics of the total reaction is complicated by several possible secondary reactions. A very coarse estimation of apparent efficiency could, however, be made by dividing the product by the energy input. The result shows that $\sim 3 \times 10^2$ mol of photon is required to reduce 1 mol of CO $_2$. This efficiency is extremely poor compared with the natural realisation of light conversion by photosynthesis. The possible reasons are: (1) antenna pigments are absent so that the cross-section of photoabsorption is small. (2) As the oxidised and the reduced products exist together in a homogeneous solution, back-reactions such as D $^+ + A^- \rightarrow D + A$, CO $_2^- + D^+ \rightarrow$ CO $_2 + D$ and others will come into effect. (3) The product is not stable and reactions such as HCOOH $\rightarrow$ CO + H $_2$ O or CO $_2 + H_2$, HCOOH + D $^+ \rightarrow$ H $^+ + 1/2$ H $_2 +$ CO $_2$ would reduce the apparent yield¹⁴. Separation of oxidising and reducing compartments by electron transport membrane would be a promising strategy to refine the present mimicked photosynthesis.

In conclusion, the results in Tables 1 and 2 indicate that the main overall reaction is the photoreduction of carbon dioxide with water as follows:

Io-U dating of the Ouljian stage from Torre Garcia (southern Spain)

IN this note we discuss the reliability of the Io-U dating method and report on the age of fossils from the Ouljian stage, outcropping along the Mediterranean coast in southern Spain. That this method can produce good results is evident from the fact that the measured ages for these fossils, all from the same stratigraphic horizon, show a standard deviation of only 6,100 yr, which is well within our precision limits. The mean age of the samples is 98,000 yr.

The dating of mollusc shells by the Io-U method has been controversial; some of the ages obtained in this way have been incompatible with other age data, and some samples from the same epoche have shown a considerable scatter in their ages. It seemed that the 'closed system' condition, a requirement for successful application of this method, is frequently violated. However, certain indications, such as the absence of ^{232}Th , and $^{234}\text{U}/^{238}\text{U}$ ratios compatible with the calculated Io-U ages suggest that little or no contamination occurred. Szabo and Rosholt¹ have proposed a model to correct for the suspected open character of the system, this model has been criticised by Kaufman *et al.*² and it seems to be of only limited interest for this study.

Although the value of the Io-U dating method is in doubt, it is the only technique available for dating events occurring between 30,000 and 250,000 yr ago. In order to test the reliability of the Io-U method we have analysed six mollusc shells which are contemporaneous—that is, they come from the same stratigraphic horizon, the Ouljian stage. The best way to check the reliability of the method is to see if the measured ages show a significant dispersion and if the calculated absolute ages are reasonable. The rocks of the Ouljian stage outcrop in Spain and North Africa; it is important to establish an absolute age for this stage to study the secular changes in the level of the sea during the Quaternary. Because the outcrops of the Ouljian at both sides of the sea of Alboran occur at different elevations, dating of this stratigraphic level provides information about recent tectonic movements in this region.

We report here on six shells from the Ouljian, outcropping in the region of Torre Garcia along the beach of the Gulf of Almeria. The Pleistocene geology of this region has been discussed by Overejo *et al.*³. Sandstones of the Ouljian, containing many *Strombus bubonius* and *Pectunculus* outcrop at a few points at 5 m above sea level; most of this formation is covered by recent dune sand. A unique level characterised by *Strombus* has been recognised⁴⁻⁶. This level has been correlated with the Ouljian stage in Morocco⁴ which was dated between 80,000 and 120,000 yr (refs 4, 7). One age of 80,000 yr has been published⁷ for a *Pectunculus* shell coming from the *Strombus* episode about 50 km NE from our sampling location at Torre Garcia. The six samples we analysed from the same horizon were cleaned mechanically; we removed about 1 mm of the superficial part. We worked mainly on the most massive parts of the shells of the *Strombus*, but for two shells, we have also analysed the thin section. All the samples were in good condition except samples I and III which had been attacked by marine organisms in some parts.

α spectrometry was used to measure uranium and thorium isotope abundances. Using the method of Goldberg *et al.*⁸, these elements in the dissolved samples were chemically separated by coprecipitation, followed by purification with organic solvents and electrodepositions. ^{232}U and ^{234}Th (a β emitter), were used as tracers. Results are shown in Table 1.

The ^{232}Th concentration was <0.001 p.p.m. in all samples; the ^{232}Th activity for the total sample (1-4 g) is barely resolvable above the background noise. It is also clear that, after the observed ^{228}Th signal has been corrected for background noise

Table 1 Analysis of six mollusc shells from the Ouljian stage

Sample	²³⁴ U/ ²³⁸ U	U (p.p.m.)	²³⁴ U (d.p.m. g ⁻¹)	I ₀ (²³⁰ Th) (d.p.m. g ⁻¹)	Age (yr)	% Aragonite
I*	1.08 ± 0.04	0.607	0.491	0.286	93,000	>90
I†	1.12 ± 0.06	0.789	0.659	0.420	108,000	>90
II	1.075 ± 0.04	0.514	0.412	0.253	102,000	Argonite > calcite
III	1.09 ± 0.04	0.846	0.689	0.414	98,000	Argonite < calcite
IV	1.09 ± 0.04	0.843	0.686	0.403	95,000	100
V*	1.12 ± 0.03	0.662	0.553	0.306	88,000	>90
V†	1.13 ± 0.04	1.03	0.875	0.534	101,000	>90
VI	1.08 ± 0.05	0.469	0.378	0.229	99,000	100

From the age values shown the mean is 98,000 yr ± 6,100 yr.
* From massive part of the shell.
† From thin part of the shell.

and the ²²⁸Th introduced via the tracer ²³²U, there is no ²²⁸Th in our samples. Of course, this is to be expected, because ²²⁸Th is a radiogenic daughter of ²³²Th. However, ²²⁸Ra (period 6.74 yr), occurs in this decay chain, and in certain situations this element is very mobile and thus the absence of ²²⁸Th suggests that no recent contamination has taken place at least by radium. Uranium concentrations range from 0.6 to 1.2 p.p.m. In shells I and V we have analysed the thin parts where the U concentration is significantly greater than in the remainder of the shell. The ratios ²³⁴U/²³⁸U are always less than 1.15 which corresponds to the value in present-day seawater. The measured ²³⁴U/²³⁸U ratios are compatible with the calculated ages for the samples to within our precision limits. The ratios in the thin parts of the shells I and V are somewhat larger than for the massive samples. The greater part of each sample is aragonitic, with calcite content less than 10%; two samples (II, IV) contain more than 10%.

The uranium concentration in the shells of living molluscs is very low, often less than 0.1 p.p.m. but in the fossil shells it can be several p.p.m. The concentrations we have measured are not very high but uranium enrichment has obviously taken place. This occurs very rapidly after the animal has died⁹: Kaufman *et al.*² have confirmed this conclusion by a statistical analysis of the uranium concentration in mollusc shells of known ages. The uranium enrichment in the shells of molluscs which have just died seems to be related to oxidation-reduction reactions occurring during the decomposition of organic material of the mollusc body. Blanchard *et al.*¹⁰ have also shown that the superficial parts of the shell are selectively enriched—conforming to our observations.

This post-mortem enrichment in uranium may cause errors of a few thousand years in dating and is thus of no great importance for our purpose. The samples may be affected by other contamination events at later stages, however. But in the present case we have no clear indication of this. For instance, contact with freshwater could cause changes in the ²³⁴U/²³⁸U ratio and in the ²³²Th abundance. Our samples (V, I) show that the uranium enrichment of the thin parts of the shells is associated with an increase of the I₀ activity. No ²³²Th activity was detected, however, so the increased I₀ activity is probably due to *in situ* production. The calculated ages of the thin parts of the shells tend to be somewhat greater than the age of the massive parts; because I₀ is not very mobile these age differences could be caused by an uranium loss occurring mainly in the superficial part. The ²³⁴U/²³⁸U ratios of all the samples are (within error limits) compatible with the I₀-U ages and hence continental water uranium contamination with its much larger ²³⁴U/²³⁸U ratio is not likely. It is also obvious that the calcite content of the shells does not show any correlation with the ages. Calcitic samples, which often contain less uranium (this is not the case here) give ages very similar to those for aragonitic samples².

Ignoring the 108,000 yr age for the thin part of shell I, which could be the result of a small loss of uranium from the outer part,

we note that the ages obtained from the remaining seven samples range from 88,000 to 102 000 yr. The mean age of these seven samples is 97,000 yr with a standard deviation of 4,900 yr. Our experimental precision is about 7%, so our results are well within precision limits. Including the 108,000 yr age, the mean age would only increase to 98,000 yr with a standard deviation of 6,100 yr. These results are in general agreement with previously obtained ages for the Ouljian⁷ but show far less scatter.

These results indicate implicitly that 98,000 yr ago the sea level was about 5 m higher, relative to the present location of the Ouljian outcrop from which our samples came. This is in contrast to sea level investigations which have indicated that the worldwide palaeo-sea level was 10 to 20 m below the present level at about 100,000 yr ago. The accuracy of our work rules out the possibility that the true age of our samples is 125,000 ± 10,000 yr, an age at which sea level was higher than today. We interpret our results to mean that the coast of the Gulf of Almeria has experienced a net upwards vertical movement of 5 m with respect to sea level and a net total uplift of 15–25 m relative to a fixed reference frame, since 98,000 yr ago, that is, 15–25 cm per thousand years.

We are grateful to M. Gigout, J. P. Cadet and J. Fourniquet for indicating the outcrop and to Y. Bottinga for review and translation of the manuscript.

Dissipation of tidal energy by Antarctic ice shelves

FLEXING of ice shelves may dissipate enough tidal energy to have a significant effect on the Moon's retreat from the Earth. It is generally agreed that tidal friction slows the rotation of the Earth and decelerates the Moon in its orbit¹. The total energy dissipated can be calculated from observations of the Moon's motion and agrees closely with estimates of the gravitational work done by the Sun and Moon on the ocean tidal bulge². Therefore dissipation of tidal energy is considered to occur mainly in the ocean with small upper limits being set on energy losses in the Earth's mantle and core. Because the amount of tidal dissipation in shallow seas³ and internal tides⁴ is uncertain it is of interest to search for additional dissipative mechanisms. In this note the possibility of tidal bending of ice shelves is examined.

An ice shelf is an ice sheet floating on the sea. In Antarctica ice shelves cover an area of $>1.5 \times 10^6$ km². Thicknesses range from 100 m at the seaward ice front to $>1,800$ m at the grounding line where the ice is attached to land⁵. Ice shelves rise and fall freely with the tide except in a bending zone near the grounding line where the ice shelf deforms. A discussion of different types of grounding line and their expected dynamic behaviour has been given by Hughes⁶. An estimate of the rate at which energy is dissipated in the bending zone can be made by assuming that ice is deforming plastically. A transient creep process with parabolic strain hardening is thought to be appropriate for stress rates occurring in tidal flexure^{6,7}. Using equations derived by Holdsworth⁷ for the surface bending stress σ , average strain rate $\dot{\epsilon}$, and exponential damping factor λ ($=\lambda p/2$ in Holdsworth's notation), the following expression can be derived for the rate at which energy is dissipated;

$$\dot{E} = \frac{2hL\sigma\dot{\epsilon}}{\lambda} = 1.24 \times 10^7 h^{29/30} \xi^{1/2} \dot{\epsilon}^{16/15} L \text{ watts}$$

where $2h$ is the ice thickness at the grounding line, L the total length of hinge line and ξ the tidal amplitude. This simply assumes that energy is dissipated at the rate of $\sigma\dot{\epsilon}$ per unit volume and that the total volume of ice affected is $2hL/\lambda$. Taking values for the Antarctic of $2h$ as 500 m, L as 16×10^3 km (ref. 8) and a semi-diurnal tidal amplitude ξ as 1 m gives $\dot{E}$ as 2.0×10^{12} W.

There are many uncertainties associated with this figure. A value for the maximum surface bending stress has been used as though it applied throughout the whole flexing region; however, on the assumption that the bending strain decays linearly towards the neutral axis the stress will decay parabolically⁷ reducing the energy dissipated by a third. The various types of grounding line are expected to have different stress patterns, but as the calculation here is for the case of least average tidal flexure strain⁶ the total dissipation is probably an underestimate. Crevasseing on the top and bottom may reduce the dissipation considerably. The length of the grounding line L includes both ice shelves and outlet glaciers and was derived⁸ from maps published up to 1965. Perhaps the greatest change to the mapped coastline of Antarctica since then has occurred on the Ronne Ice Shelf⁵. However, although the position of the coast has been altered, there has been little change in the actual length of coast. The greatest error probably lies in not considering ice rise boundaries, and thus the figure used should be regarded as a lower bound. There is more uncertainty in the value used for the mean thickness of ice at the hinge zone. Although the major ice shelves have at least some depth soundings, data for grounding line regions are sparse. Using published ice thickness contour maps for the Ross Ice Shelf⁹ and the Ronne Ice Shelf⁵ (excluding the Filchner Ice Shelf), their mean thickness at the grounding line can be calculated as 610 m and 990 m respectively. These

two ice shelves contain a quarter of the total length of grounding line. Another approach is to take the mean thickness of all Antarctic ice shelves, 390 m (ref. 8), so that by assuming a value for the mean thickness at the ice front where the ice is thinnest the mean grounding line thickness can be estimated. Taking a value at the ice front of 200 m gives the mean thickness at the grounding line to be 580 m. So again, the actual figure of 500 m used in the calculation probably errs on the side of caution. The dissipation rate of 2.0×10^{12} W is unlikely to be underestimated because of errors in h and L . A reasonable error, considering the competing nature of all the uncertainties, might be of the order of 50%.

One way of checking whether this amount of dissipation by bending is feasible would be to estimate the total tidal energy flux under ice shelves. In general, the energy flux per unit area perpendicular to the direction of propagation is given by $\frac{1}{2}\rho g u \xi \cos \theta$ where ξ and u are the amplitudes of tidal height and current respectively. For a progressive wave $\theta = 0$ and the maximum current flow inwards occurs at high tide; for a standing wave $\theta = \pi/2$ and there is no net energy flux. Again, because of the almost complete lack of relevant data for Antarctica it is impossible to perform a meaningful calculation. However, if the energy flux under a section of the Filchner Ice Shelf, where a value of tidal current of 0.1 m s^{-1} is assumed¹⁰ for a site where the depth of the water column under the ice front is 600 m (ref. 11) is taken as typical for the rest of Antarctica, then for $\theta = 0$ the required energy flux would be provided by only 6.6×10^3 km of ice front. It is therefore reasonable to say that there is probably enough incoming energy to allow the dissipation rate calculated for tidal bending.

To account for the astronomically observed lunar acceleration a dissipation rate of $5.7 \pm 0.5 \times 10^{12}$ W is required². This is close to the estimate of $5.0 \pm 0.3 \times 10^{12}$ W for the work done on the ocean surface by the luni-solar torque². The problem is to determine how the dissipation occurs in the ocean and to partition the energy loss among the mechanisms. An estimate of the frictional losses in shallow seas and continental shelves³ is $1.5 \pm 0.8 \times 10^{12}$ W. However, many of the areas where dissipation occurs are situated in high latitudes where the main tidal torque is reduced by a factor $\cos^2 \psi$ where ψ is the latitude¹². The same problem applies to ice shelf dissipation. It is uncertain how dissipation in high latitudes and in localised regions can affect the rest of the ocean tide. A more even dissipation of tidal energy would be by internal (baroclinic) tides, but an estimate of the energy loss is of the order of 10% of the total tidal dissipation⁴. After allowing for errors the total dissipation from these three mechanisms can therefore barely account for the required amount.

If tidal energy is being lost under ice shelves then one might expect to find that the age of the semi-diurnal tide is high. The age of the tide is the time interval between the time of new or full Moon and the time of the spring tide. Other areas of the ocean where the age of the tide is greater than 60 h are associated with strong tidal dissipation¹³. There are few reliable tidal records from Antarctica but the majority show ages greater than 60 h. The most detailed analysis has been carried out by Cartwright¹⁴ on records gathered along the west coast of the Antarctic Peninsula for observation periods of up to 9 yr. The results clearly show increasing age of tide with latitude, culminating in ages of 165 h for tidal records obtained on George VI Ice Shelf. Gravimetric readings on the Ross Ice Shelf also show a very high age of the semi-diurnal tide but with small amplitudes¹⁵. Conversely, the lowest age found in Antarctica (17 h) has been measured on the edge of the Filchner Ice Shelf¹⁶. This may be an indication of the complexity of the interaction between ice shelves and tides especially near critical latitudes where tidal and inertial frequencies are equal¹⁴. In principle the energy flux under an ice shelf could be calculated from simultaneous measurements of tidal amplitude and current. It would then be possible to decide the importance of tidal dissipation both by bending and by frictional losses along the bottom of the ice shelf and the bottom of the sea.

If ice shelves form a major sink for tidal energy then there are implications on a geological time scale. It might be expected that the times of maximum slowing of the Earth's rotation would coincide with times of maximum extent of ice shelves. Within the constraints imposed by the lack of data, this seems to be the case; extensive glaciation occurs in the periods preceding 'turning points' when the Earth increases its spin velocity¹⁷.

Melting of Antarctic icebergs

PROPOSALS for supplying water to arid regions through the towing and utilisation of Antarctic icebergs^{1–5} have generated considerable interest. Simulation studies on the towing of unprotected icebergs to southern continents⁶ suggest that the towing distance, ocean currents and the iceberg deterioration rate are of major importance. The distance and current components may be optimised by a careful choice of iceberg position, although much further study of currents in southern latitudes is required. The rate of deterioration is probably more difficult to calculate as a number of melting and calving mechanisms may be operating. In this note some initial studies of iceberg melting are reported and some of the problems involved in further investigations are considered.

Above-sea surface melting is probably due to solar radiation and wind-enhanced convection. Under-sea melting may occur through turbulent natural convection. This should be increased by iceberg surface discontinuities, iceberg wallowing or by release of entrapped air bubbles on melting. Calving could result from side undercutting by wave action⁷, differential melting along cracks and low density areas⁸, stress on underwater shelves formed through layered melting⁹ or thermal stress-induced disintegration following calving in warm water⁶.

If under-sea melting is an important ablation mechanism, then one or more of the following three effects might be detectable. (1) The lighter freshwater could rise up the sides of the iceberg with little mixing to produce a pool of less saline water. If this happens then it would be possible for meltwater to be collected in warm waters by building a shallow pen around the iceberg. (2) The lighter freshwater may entrain warmer, saltier water from the surrounding sea and thus be responsible for considerable vertical transport of deep water and nutrients¹⁰. (3) Melting could occur in a stratified manner and the freshwater may then disseminate in layers. This type of melting has been detected in model studies⁹.

Thus evidence of gross salinity variation near an iceberg would support mechanism (1), and a temperature rise would support mechanism (2). To test for these two mechanisms,

salinities were measured around three icebergs in the northern Ross Sea/Southern Ocean. (Mechanism (3), suggested only recently⁹, was not tested. The salinity changes involved would probably not be detectable with the small portable salinometer used.)

All measurements were made from the 18-m yacht Solo using a Yellowsprings Instruments portable salinity/temperature meter (sensitivity, $S = \pm 0.05\%$), equipped with 200 m of cable. Salinities were recorded in the open sea in the following conditions. (1) Motoring as close as safety permitted (20 m from underwater ram) on the lee side of an iceberg; as the yacht drifted slowly downwind, measurements were taken continuously. (2) Circling an iceberg (speed ~ 2 knots) at known distances (closest weather side measurements were at 60 m). The meter was standardised at ambient temperature before use with a standard seawater solution¹¹. Salinity data were gathered at distances of 20 m to 800 m (range under values) and at depths of 5, 10, 25, 60, 100 and 200 m. A correction for drag on the weighted probe was not applied but depths are probably overestimated by no more than 20%.

The results are shown in Table 1. No variation of salinity with distance from icebergs was found. A temperature inversion at a depth of 50–60 m around iceberg no. 3 was recorded but this extended for at least 2 km. Again, no salinity variation with distance was detectable along this discontinuity.

It is perhaps not surprising that there was no evidence of a salinity gradient with distance around icebergs, even in water to $+5.6^\circ\text{C}$. It seems likely that naturally positioned icebergs are not melting rapidly or that if melting is substantial then either mixing or rapid layered spreading may occur. If only little melting is occurring this might be because of the formation of a narrow insulatory envelope of cold water. Disturbance of such an interface by iceberg towing would then increase the melting rate dramatically. Unambiguous results will probably only be achieved by using a more accurate meter very close to an iceberg (possibly a dangerous undertaking).

No salinity step structure like that observed in the Weddell Sea¹² was observed, but a more accurate meter might detect such salinity steps in this region of ocean. However, a gross thermal inversion at 60 m was observed near iceberg 3. This thermal inversion is large for waters south of the Antarctic Convergence. Similar salinity profiles without step structure have been maintained in tanks with sloping boundaries¹³. Rapid changes in surface sea temperature at the Antarctic Convergence were measured further north at 59°S , 163°E . The lack of a shallow warm surface layer in the regions studied may be due to consistently overcast, cold, foggy weather.

however, have been attributed to the Putjangan Beds with reasonable certainty¹⁹⁻²¹.

Weidenreich²² studied the Javanese hominid fossils and suggested the following evolutionary trend, based on their morphological characteristics: *Meganthropus palaeojavanicus* → *H. modjokertensis* (which he named *robustus*) → *H. erectus*. Some hominid fossils from Late Pleistocene sediments, associated with the Ngandong mammalian fauna, correspond to an advanced *H. erectus*, or the *Neanderthal*²³. Tobias and Von Koenigswald²⁴ compared hominid fossils attributed to the Putjangan Beds with fossils from Olduvai Gorge. They concluded that *H. modjokertensis* (IV and B) is similar to *H. habilis* (Hominid 13) from the lower part of the Olduvai Bed II, while *M. palaeojavanicus* is similar, but a somewhat more primitive form than *H. habilis* (Hominid 4) from Olduvai Bed I (Fig. 1). This correlation is in agreement with Weidenreich's²² evolutionary trend of the Javanese hominids. *H. dubius*^{20,21} may represent, according to Von Koenigswald²¹, the earliest form of hominids recovered from Java. A K-Ar age of 1.9 ± 0.4 Myr has been obtained for the Putjangan Beds near Modjokerto, a few metres below the level where the skull of *H. modjokertensis* was recovered^{25,26}. Thus, the available data compiled in Fig. 1 suggest that the boundary between the Kabuh and Putjangan Beds may be tentatively placed about the middle of Bed II of Olduvai Gorge, and that the base of the Putjangan Beds in Eastern Java is older than the 1.8 Myr fossiliferous level of the Olduvai Gorge Bed I.

continental beds. As Reinhold²⁷ pointed out, the diatoms in these various units largely reflect the gradual emergence of Java. Previous work by us^{28,29} has tied Late Pliocene and Pleistocene stratigraphic events (datum levels) in the Tropical Indo-Pacific to the palaeomagnetic reversal and oxygen isotope records^{30,31}. The use of these two standards tied to diatom datum levels permits us to draw correlation lines for the Late Pliocene and Pleistocene of the Tropical Indo-Pacific with a high degree of reliability. Within this context, we studied the marine diatoms in Reinhold's original samples from the Upper Kalibeng Beds and from the marine intercalations in the overlying Putjangan Beds (Fig. 2). These were compared with diatom ranges in a central Pacific core (V28-179) which has an expanded Late Pliocene section and which has been analysed for palaeomagnetism and oxygen isotopes³¹. The lower part of the Upper Kalibeng Beds contains *Rhizosolenia praebergonii*, *R. praebergonii* var. *robusta*, *Thalassiosira convexa* and *Th. convexa* var. *aspinosa* suggesting a correlation with the basal part of the Matuyama Reversed Epoch. The upper parts of the Upper Kalibeng Beds, on the other hand, contain only two stratigraphic markers (*R. praebergonii* and *R. praebergonii* var. *robusta*), thus placing it after the last appearance of *Th. convexa* and *Th. convexa* var. *aspinosa*. The absence of *Pseudoeunotia doliolus* and of the recurring species *Coscinodiscus nodulifer* var. *cyclopus* suggests that the contact between the Upper Kalibeng Beds and the Putjangan Beds (and, thus, the transition between marine and non-marine sediments) should be dated after the last occurrences of *Th. convexa* and *Th. convexa* var. *aspinosa* and *C. nodulifer* var. *cyclopus* and before the first appearance of *P. doliolus* and reappearance of *C. nodulifer* var. *cyclopus*. Within this context, our data suggest that the base of the Putjangan Beds in Eastern Java falls between approximately 1.9 and 2.1 Myr.

As the earliest hominid fossils occur in lake sediments of the Putjangan Beds which overlay Pliocene marine sediments, early man must have migrated to Eastern Java soon after the local emergence. The age of 1.9–2.1 Myr given by diatom analysis for this emergence must be considered tentative, however, pending more detailed sampling for micropalaeontologic and palaeomagnetic study. Further, since the uplift of Java proceeded from west to east⁸ a micropalaeontological and palaeomagnetic study of the marine/non-marine transition in several sections could provide us with a more detailed history of the emergence of this island during the Late Cainozoic³¹.

We thank G. Kukla, N. D. Opdyke and N. J. Shackleton for discussions. This work was supported by grants from the NSF (OCE76-18049, OCE76-80690, and OCE75-18136) and the Office of Naval Research (N00014-75-C-0210).

Minor metal content of surface seawater particulates and organic-rich shelf sediments

CERTAIN sediments deposited under areas of high primary productivity contain considerably more organic carbon than those laid down in other marine environments; for example, diatomaceous clays on the continental shelf off South-West Africa (Namibia) have an average of 9% organic carbon¹. Calvert and Price² have reported that these sediments also have enhanced concentrations of some trace metals, such as Cu, Zn and Pb. During the past few years we have been carrying out collections of surface (0–5 m) seawater particulates from various areas of the World oceans^{3–6}. Here, we present average data on the concentrations of Al, Cu, Zn, Pb and organic carbon in a series of particulates collected off the coast of West Africa, and compare them to organic-rich marine sediments.

Calvert and Price compared the modern environment of organic-rich sedimentation on the continental shelf of Namibia to that prevalent during the deposition of some ancient bituminous shales. According to Brongersma-Saunders^{7,8} the enrichment of Cu, Pb and Zn in many of these deposits, such as the Permian Kupferschiefer of northern Germany, is the result of their supply by plankton in regions of upwelling. However, Calvert and Price² found that the concentrations of Cu, Zn and Pb in the sediments on the South-West African shelf were not enriched to the same extent as in the Kupferschiefer, and concluded that the same mechanism of trace element deposition had not been operative in the two areas. Nonetheless, Calvert and Price² found a high degree of correlation between the Cu, Pb and Zn and the organic carbon concentrations in their sediments, and suggested that the metals were intimately associated with the organic fractions of the deposits. They stressed, however, that before the mechanism of deposition could be identified, more data were required on the relative contributions made to the total metal concentrations by biogenous, terrigenous and authigenic sources. In this respect, the concentrations of Cu, Zn and Pb in the suspended material of the overlying waters is of critical importance. Data have been

Table 1 The partial element average compositions (p.p.m.) of South-West African shelf sediments and northeastern Atlantic surface water particulates

	12 Northeastern Atlantic particulates	Diatomaceous clay South-West African shelf*
Al	9,700	15,446
Cu	112	68
Zn	225	68
Pb	50	12
Organic C	219,000	93,500

*Data from Calvert¹.

provided on the trace metal contents of plankton from various regions of the World oceans⁹, and although the metal concentrations vary considerably from one region to another certain overall enrichment trends are apparent. However, there is a general lack of information on the composition of total particulate material, a mixture of lithogenous, hydrogenous and biogenous components, from regions of high primary production.

We made particulate collections by a continuous centrifuge technique described elsewhere⁶; Cu, Zn, Pb and Al were determined by either atomic absorption or spectrographic methods, and organic carbon was measured using a C–H–N analyser. The samples selected for the sediment comparison were all collected on transects within ~500 km of the coast of West Africa between 8 and 30° N, during April, July and October 1972 and February 1973.

None of the particulates were collected off the coast of South-West Africa. However, the sample transects were chosen such that they are all within the general region of high primary production lying off the coast of West Africa (5–30° N)¹⁰. The particulates should, therefore, offer a reasonable comparison with the organic-rich South-West African shelf sediments if theories of planktonic sedimentation are to have a general ocean-wide application to the genesis of organic-rich near-shore sediments and their lithified equivalents. In other words, the two data sets, that is, those of the particulates and the shelf sediments, can be used to test the geographical independence of the general mechanisms which result in the correlation between organic matter and certain trace metals in sediments underlying areas of upwelling.

Table 2 The maximum minor element/organic carbon ratios in South-West African shelf sediments and the average ratios in northeastern Atlantic surface water particulates

Element/organic carbon (% × 10 ³)	Northeastern Atlantic particulates	Diatomaceous clays, South-West African shelf*
Cu	0.51	0.56
Zn	1.0	1.8
Pb	0.23	0.29

*Data from Calvert and Price².

The average concentrations of Cu, Zn, Pb, Al and organic carbon in the South-West Africa shelf sediments and the northeastern Atlantic particulates are given in Table 1. This shows that the sediments are not composed simply of settled undifferentiated bulk samples of the surface water particulates. For example, the sediments have a much larger 'terrestrial' component, represented by Al, and a much smaller 'planktonic' component, represented by organic carbon, than do the particulates. This is not unexpected because of the various diagenetic processes which affect the deposited sediments. However, in addition to bulk samples, Calvert and Price² have given data on the maximum concentrations of Zn, Cu and Pb in the sediments, together with that of organic carbon. If these maximum values are assumed to offer the best available estimate of the extreme situation in which the plankton have retained their original composition, they can be directly compared to the surface water particulates. Such a comparison is made in Table 2, from which it can be seen that the metal/organic carbon ratios in the particulates are similar to those in the maximum metal-enriched sediments.

The initial composition of plankton-rich surface water particulates is usually considerably modified, after deposition, by diagenetic processes. However, the data presented here strongly suggest that modern organic-rich sediments underlying regions of high primary production can receive a substantial proportion of their Cu, Zn and Pb from the sinking of relatively undifferentiated surface water particulates of which organic components,

including plankton and faecal pellets, are an important constituent.

We thank the Blue Funnel Line for permission to make collections from their ships, the Master, officers and crew of the MV Cyclops, and the NERC for financial support.

Diversity in constant and fluctuating environments

It has been suggested that environmental fluctuations will limit the degree to which species may be packed; the closeness of the packing increasing with increasing environmental stability¹. This theory has been challenged by the suggestion that although there is a limit to the degree of niche overlap in the real world, the limit is only sensitive to severe environmental fluctuations². The fluctuations are regarded as severe when their variance to mean ratio is greater than or equal to 0.3 (ref. 2). We report here our studies on populations of ciliate protozoa of a freshwater community maintained in temperature-controlled microcosms. Comparisons were made between the changes in diversity of the ciliates in a microcosm maintained in a fluctuating temperature and the changes taking place in a control maintained at a constant temperature. The results suggest that the diversity of the ciliates is significantly greater in the fluctuating-temperature system than in the constant-temperature system.

Samples of water were taken from Sand Loch, Aberdeenshire (grid ref. NJ 034284), and brought back to the laboratory. The water was filtered to remove large pieces of debris before being put into the experimental system. (The mesh of the filter was square, with sides of 250 μm .) Two sets of samples were collected, the first in January 1978 (experiment 1) and the second in April 1978 (experiment 2).

The water samples were maintained in batch culture in four 20-l flasks, which were kept in one of two water baths, the temperature of each being independently thermostatically controlled. The fluctuating environment was created in one bath by daily variations in the temperature (Figs 1 and 2) ranging over 2–12 °C, with a complete cycle of variation occurring every 2 d. The control system was maintained at 7 °C. In each system, samples were taken from one flask while the other acted as a reservoir to maintain a constant culture volume in the sampled vessel. A sample of 0.25 l was taken from each system daily and sedimented overnight according to the method described by Lund, Kipling and LeCren³. The ciliates present in each sample were identified (to genus level) and counted during the day after

Fig. 1 Changes in temperature and diversity with time during expt 1. The lower graph shows the change in diversity ($\log_{10} \alpha$) with time (d) for the fluctuating-temperature system (○) and for the constant-temperature system (●). The upper graph shows the change in temperature (°C) with time (d) for the two temperature regimes, fluctuating temperature (○) and constant temperature (●).

sampling. The diversity of the ciliates present in the cultures was estimated using the log-series parameter, α (Figs 1 and 2). This index was used in preference to the Shannon–Wiener information index⁴ because the former does not overemphasise the presence of the commonest taxa to the same extent as the latter^{5,6}. Also, it has been shown that the site-discriminating ability of α is superior to the information index⁵ and is, therefore, more applicable in this type of investigation.

Determination of the between-system to within-system variance (Table 1) showed that variation between the diversity of the ciliates in the two temperature regimes was significantly greater than that within each of the two systems in both experiments ($P < 0.01$ in experiment 1, $P < 0.05$ in experiment 2). The diversity of the two ciliate populations did not differ significantly initially, but it was found that over a period, the diversity of the ciliate populations in the fluctuating-temperature system was significantly greater than that of those maintained in a constant temperature (in both experiments $P < 0.01$). A Spearman rank correlation showed that in the first experiment there was no correlation between the diversity of the ciliate populations in either temperature system and time, but that in the second experiment, there was a significant positive correlation between diversity and time for both ciliate populations ($P < 0.01$). These differences may be accounted for by the differing composition of the ciliate populations due to seasonal variation in the freshwater community.

The results obtained from both these experiments suggest that, in the conditions of these experiments at least, deterministic perturbation of an environmental factor leads to a

Fig. 2 Changes in temperature and diversity with time during expt 2. Expt 2				4.8†

* $P < 0.01$.† $P < 0.05$.

greater diversity of the ciliate population. The decreased index of diversity in the constant-temperature system is due to the increasing relative abundance of a small number of genera which dominate the ciliate populations. In the fluctuating-temperature system the relative abundances of the genera present are comparatively lower than those in the control system, and domination of the ciliate populations by a small number of genera does not occur to the same degree. It would seem that in the fluctuating-temperature system the environmental variations may be reducing the number of individuals present such that competition plays only a minor part in population control, thus leading to more even abundances of the genera present. In contrast to this, the constant-temperature system has allowed the part played by competition in population control to increase, such that a few genera have competitively excluded the others and so have become dominant in the ciliate population.

This reasoning is supported by Connell's assertion⁷ that the high species diversity of tropical rain forests and coral reefs is caused by infrequent catastrophic environmental perturbations which keep the community in a nonequilibrium-nonclimatic state, thus reducing the chance of elimination of less-able competitors, as is suggested by these experiments which use deterministic and less extreme perturbations.

This work was carried out during the tenure of a research studentship from the Natural Environment Research Council to J.C.E.

Attraction of the tick *Ixodes neitzi* to twigs marked by the klipspringer antelope

THE klipspringer (*Oreotragus oreotragus*), a small African antelope which lives in specific rocky outcrops, secretes a dark pungent resin-like substance from the ante-orbital glands which is utilised as a means of intraspecies communication¹. Marking is carried out by rubbing the ante-orbital glands on a substrate such as the twigs of shrubs on which the secretion is deposited. We have now observed that the adults of the tick *Ixodes* (*Afrimex*) *neitzi*² aggregate on twigs which have been previously marked by the klipspringer (Fig. 1). The attractive component of

the secretion is water soluble. The capability of the adult tick to detect the klipspringer scent was demonstrated in field observations and with laboratory experiments.

Adults of *I. neitzi* were collected from shrubs in the Rhodes Matopos National Park, Rhodesia. *Securinea virosa* was the dominant plant species in this area and grew from cracks in the rocks or closely to rocks.

The effect of the resin-like secretions collected from the twigs was assessed using the petri dish technique³ with minor modifications. Each 9-cm Petri dish was marked into eight sectors and because *I. neitzi* were very sensitive to desiccation, moistened discs of filter paper were placed in each sector. At the start of each experiment, 10 ticks (male or female) were placed in the centre of the petri dish. The tested materials were always placed in sector No. 8. A concentrated aqueous extraction of twigs marked by the klipspringers was the only substance which significantly attracted the ticks (Fig. 2).

Further examination using a Y-shaped olfactometer^{4,5} showed that none of the substances tested were attractive ($P < 0.5$, t -test for paired observations). The failure of the ticks to detect extract in the olfactometer and the fact that *I. neitzi* adults did not aggregate around freshly applied deposits which had been moistened, suggest that the scent secretion of the klipspringer is not airborne and only becomes attractive to the ticks or any other arthropods after a copious amount of water had been applied to the extract.

The solid secretion was extracted with different solvents and only the water soluble fraction was active in attracting the ticks (Fig. 3).

Fig. 1 a, Illustration of a twig marked by scent secretion from the ante-orbital gland of klipspringers. b, Assembly of *Ixodes neitzi* adults to a marked twig.

Uncontaminated branched twigs from the same shrubs from the experimental area were selected. The base and left arm of the Y-shaped twigs were painted with a concentrated aqueous solution prepared from marked twigs collected in the field. The Y-shaped twigs were positioned in soil with the two arms pointing upwards. Adult ticks were released on the soil and allowed to migrate. As the ticks moved up the vertical structure they were able to select one of the arms of the twigs.

These experiments were conducted in the field and repeated in the laboratory. In the field $66.2 \pm 2.9\%$ ($P < 0.001$) of the adults released in the vicinity of the Y-shaped twigs ascended the arm on which the aqueous klipspringer scent extract was applied. In the laboratory similar results were obtained where $63.7 \pm 1.00\%$ ($P < 0.001$) of the adults selected the treated arm. With similar but untreated Y-shaped twigs $52.2 \pm 2.08\%$ ($P < 0.3$) of the adult ticks selected the left arm.

In some *Ixodes* species an assembly pheromone has been shown to be secreted before feeding commences^{6,7}. To exclude any possibility of prior contamination of the marked twigs with a tick assembly pheromone, an aqueous extract was made from the ante-orbital glands of a klipspringer. When this material and

Fig. 2 Average assembly response (% $\pm$ s.e.) of *Ixodes neitzi* females ($\square$) and males ($\boxtimes$) to various materials placed in sector 8. *a*, Concentrated aquatic extract (30%) of scent marks of klipspringer. *b*, Dilute aquatic extract (10%) of scent marks of klipspringer. *c*, Scent marks of klipspringer which had been dipped in water before the experiment. *d*, Solution of unmarked twigs (control).

an aqueous extract of marked twigs were compared no differences were found, showing that the attractive principle arose from the klipspringer orbital gland secretions and excluding the possibility of pheromone contamination from the tick.

The klipspringer exudate apparently solidifies rapidly after being deposited on the tips of the twigs (Fig. 1a). This substance is subjected to the heavy rains falling between November and March (800 mm). The active component dissolves in the water, drips or runs down through the branches and stems to the

Fig. 3 Average assembly response (% $\pm$ s.e.) of *Ixodes neitzi* females ($\square$) and males ($\boxtimes$) to various materials placed in sector 8. *a*, Water soluble fraction of the scent marks of the klipspringer. *b*, Methanol soluble fraction of the scent marks of klipspringer.

ground level. We assume that the adult ticks, probably by using a gustatory sense, respond to the extract and follow it to the tip of the twigs. The adults remain inactive on the twigs until the return of the klipspringer to re-mark the area. Sniffing of the marked twigs by the klipspringer and consequent physical movement of the shrubs, stimulate the tick to gain access to the host.

This constitutes the first report of a tick species locating its mammalian host by detecting a specific chemical compound or compounds, used by the host as a communicative marking signal, thus increasing its probability of survival in that particular habitat.

We thank Professor G. B. Whitehead, Dr T. Choate and Dr G. F. T. Child for their assistance and Professor G. B. Whitehead for reviewing the manuscript.

Mixed ligand chelate therapy for plutonium and cadmium poisoning

SERIOUS environmental and industrial hazards are associated with the release of radioactive¹⁻³ and nonradioactive⁴⁻⁷ metals. Most treatments for acute and chronic metal poisoning use chelating agents forming soluble, stable and excretable metal complexes¹⁻⁹. Although a few chelants are used clinically⁸, the efficacy of single-chelant therapy and variations is limited¹⁻³ and deleterious effects can occur^{4-7,9,10}. Consequently, Schubert recommended^{11,12} the use of mixed-ligand chelates (MLCs), in which the metal binds two or more different chelants, because of the enhanced stabilities attainable. For example, formation constants of thorium MLCs can exceed that of EDTA alone by at least 10^{13} (refs 13-15). We report here hitherto unparalleled achievements using MLC treatment, namely, complete removal of tissue deposits of ²³⁹Pu and prevention of mortality in animals given lethal, $>LD_{100}$, doses of cadmium.

Female, HA(ICR) mice, 45 d old, weighing 25.1 ± 0.6 g, were injected intravenously with plutonium or cadmium solutions; chelants were usually administered intraperitoneally. Monomeric¹⁶⁻¹⁸ ²³⁹Pu(IV) in 1% sodium citrate and cadmium chloride with and without addition of ¹⁰⁹Cd were used. Radiochemical assays¹⁹ were made from wet ashed tissues and excreta, and the activity measured in a liquid scintillation counter.

Table 1 Effect of single and mixed ligand chelate treatment on the tissue levels and total excretion of ^{239}Pu in female mice after Pu administration

Sample	% Of injected dose of ^{239}Pu				
	Untreated controls	SA(2.0)	DTPA (0.5)	DTPA (2.5)	DTPA + SA (0.5 + 2.0)
Urine	4.3	5.4	24.8	28.4	54.0
Faeces	28.2	26.2	41.4	44.6	46.6
Liver	5.4 ± 0.3	5.1 ± 0.5	0.33 ± 0.1	0.22 ± 0.1	0 ± 0.01
Skeleton	33.7 ± 1.3	33.5 ± 2.1	13.8 ± 0.5	13.6 ± 0.4	0 ± 0.1
Total	71.6	70.2	80.3	86.8	100.6
Body (calculated)	67.5	68.4	33.8	27.0	0

The chelate treatment shown is in mmol per kg, and was given twice weekly. Measurements were taken 33 d after Pu (0.0162 μCi per mouse) administration and 30 d after the onset of treatment. The liver and bone levels represent average values $\pm$ s.d. from six mice, and the urine and faeces represent values per mouse from analyses on pooled samples from three mice. The total skeletal content was obtained by multiplying the amount of Pu in both femurs by 12 (refs 17, 18). The body values were calculated by subtracting the urine + faecal values from 100. See text and legends to Figs 1 and 2 for experimental details.

Polyaminopolycarboxylic acids (PAPCs) were administered as calcium-sodium salts to prevent hypocalcaemia, and components of MLCs were pre-mixed, that is, injected as a single solution.

Three days after Pu administration, when almost all had been deposited in the tissues^{16-18,20}, twice weekly injections of MLC [diethylenetriaminepentaacetic acid (DTPA) and salicylic acid (SA)] and of the individual chelants were initiated. Daily urinary excretion (Fig. 1) demonstrated that DTPA + SA increased Pu excretion to levels far above those induced by DTPA alone; SA alone had no effect (Fig. 1). By day 33 post-Pu, all injected Pu had been eliminated in urine and faeces (Table 1). After 10 treatments with massive doses of DTPA, skeletal Pu remained at 15% of the injected dose, whereas that of DTPA + SA-treated mice was, within counting statistics, free of Pu (Fig. 2 and Table 1). The livers of MLC-treated mice were devoid of Pu after four treatments. When treatment was delayed until 6 d post-Pu, 12 DTPA treatments reduced skeletal Pu to $24.3 \pm 0.3\%$, in agreement with previous work²¹, compared to $1.4 \pm 0.2\%$ of injected dose after 12 MLC treatments.

Fig. 1 Effect of single and mixed ligand chelates on the daily urinary excretion in female mice of plutonium-239 (specific activity $0.063 \mu\text{Ci} \mu\text{g}^{-1}$). The background count was 23.0 ± 0.5 d.p.m. Each point represents ^{239}Pu values per mouse from pooled samples of three mice. The animals were given a single intravenous injection of monomeric Pu(IV)-citrate of $0.0162 \mu\text{Ci} = 35,600$ d.p.m. The counting efficiency was almost 100%, as determined with calibrated standards. Three days later, treatment by intraperitoneal injection began and continued twice weekly. The DTPA was administered as the CaNa_3DTPA salt and that of SA as the sodium salt. The DTPA + SA were pre-mixed and injected as a single solution. ●, DTPA + SA (0.5 mmol per kg + 2.0 mmol per kg); □, DTPA (2.5 mmol per kg); ■, DTPA (0.5 mmol per kg); ▲, SA (2.0 mmol per kg); ○, Pu controls; arrows indicate treatment.

In experimental, acute Cd poisoning, DTPA or EDTA are marginally effective^{2,3,22-25}, and dimercaptopropanol is contraindicated^{4,8,25}. MLC treatment of mice 1 h post-Cd with EDTA + SA or EDTA + 2,3-dimercaptopropanol-1-sulphonate (Dimaval) (DMPS) resulted in 100% survival, whereas all single-chelant-treated animals died (Fig. 3). The therapeutic effect of the MLCs reflected a strong decorporative action. Thus, after a dose of ^{109}Cd -labelled chloride which was 4.5 times the LD_{100} , a single EDTA + SA injection 1 h later removed 82% of the Cd present in the kidneys at the onset of treatment; EDTA was ineffective.

The effectiveness of MLC therapy is maintained when low, clinically accepted doses¹⁻³ are used; for example, 0.05 mmol per kg for PAPCs and 0.2 mmol per kg for secondary chelants. The MLCs are also effective when administered orally. Many

Fig. 2 Effect of single and mixed ligand chelate treatment on the concentration of ^{239}Pu in the skeleton of female mice. Each point represents the average value of analyses made on the femurs of each of six mice. The skeletal values were obtained by multiplying the femur values by 12 (refs 17, 18). As the skeletal levels of ^{239}Pu for DTPA doses of either 0.5 mmol per kg or 2.5 mmol per kg were almost identical, one symbol was used for both. The SA dose was 2.0 mmol per kg, and the MLC was 0.5 mmol per kg DTPA + 2.0 mmol per kg SA. The error bars represent the standard deviation and are not included when the symbol diameter exceeds the magnitude of the standard deviation. Treatment with single or mixed ligand chelants began 3 d after the intravenous injection of $0.0162 \mu\text{Ci}$ of ^{239}Pu in the monomeric citrate form. Further experimental details are given in the text and legend to Fig. 1. ○, Pu controls; ▲, SA; □, DTPA; ●, DTPA + SA; arrows indicate treatment.

Fig. 3 Effect of treatment with single and mixed ligand chelates on the survival of female mice given increasing doses of cadmium. Each point represents the % survival of a group of at least 20 animals. The mice were given a single injection in the tail vein, of an aqueous solution of $\text{CdCl}_2 \cdot 2.5\text{H}_2\text{O}$ (MW 228.3). One hour later each mouse received a single, intraperitoneal injection of the specified chelant or mixed chelant solution. The untreated controls received a single i.p. injection of isotonic saline solution. Animals which survived 3 d remained healthy for the remainder of the observation period (4 weeks). ●, EDTA+SA or EDTA+DMPS; □, EDTA; ▲, SA; ■, DMPS; ○, Cd controls.

MLCs consisting of PAPCs with bidentate aromatic compounds or other bidentate compounds or PAPCs are at least as effective for Pu decorporation and therapy of other metals including Cu, Zn, La, Fe(III), Ni, Pb and Th, (these MLC systems include EDTA or DTPA combined with 1,2-diamino-cyclohexanetetraacetic acid, dithiocarb, hydroxyethylene-diaminetriacetic acid, nitrilotriacetic acid, penicillamine, salicylhydroxamic acid, sulphosalicylic acid and Tiron.) We are also investigating combinations of MLCs for decorporation of polymeric and insoluble forms of plutonium and other metals largely resistant to single-chelant treatment¹⁶⁻¹⁸ by using Fe-effective MLCs to facilitate decorporation of metals, for example, Pu, associated with endogenous iron species such as transferrin and ferritin.

Many chemical considerations play a part in the choice of MLC systems. For example, for 6-coordinate Cd(II), the MLC of EDTA+SA (total dentateness 8), as anticipated²⁶⁻²⁹, is more effective than DTPA+SA (total dentateness 10), as the presence of four unbound carboxyl groups in DTPA+SA, compared to two in EDTA+SA, is de-stabilising. The greater stability of many MLCs, larger than that predicted from statistical factors^{30,31}, derives^{13-15,26-31} from charge neutralisation, steric effects, intramolecular electrostatic interactions and cooperative electronic effects, particularly with aromatic secondary chelants. As the secondary chelant alone was largely inactive, we conclude that the primary metal chelate facilitates incorporation of the secondary chelant, presumably by deprotonation.

Experimental evidence of *in vitro* and *in vivo* formation of MLCs is provided by different chemical and biological approaches. When the total dentateness of the chelants was less or greater than the ligancy of the metal ion, for example, the metal chelates were hydrophilic, but they were lipophilic when the total dentateness was equal. Experimentally, we found that Pu(EDTA), Pu(SA) and the MLC of Pu(DTPA)SA were indeed hydrophilic, and that Pu(DTPA) and Pu(EDTA)SA were lipophilic as determined from partition coefficients using H_2O as the polar phase and *n*-heptane as the nonpolar phase. Ultrafiltration experiments^{11,12,32} on liver homogenates containing Pu or Th demonstrated greater effectiveness of MLCs relative to single chelants, and the superiority of EDTA+catechol (CAT) or DTPA+CAT relative to EDTA+SA or DTPA+SA, in agreement with potentiometric titration studies¹³.

In vivo MLC formation was demonstrated with yeast-fermented rats³³ in which varying concentrations of injected Zn(EDTA) or Cu(EDTA) reduced salicylate antipyresis to a predictable, quantitative degree³⁴. Removal of endogenous metals such as Zn by MLCs is similar to that by EDTA and DTPA (refs 2, 35-37), but treatment twice weekly, because of dietary replacement, produced no toxic symptoms. Toxicological and pharmacokinetic studies on MLCs using ^{14}C - and ^3H -labelled compounds are underway.

Mixed ligand chelate or complex formation by naturally occurring ligands and metals enters into biochemical processes and environmental situations, such as transport of metals from soils into the food chain and ground water. The ability of MLCs to remove all ^{239}Pu permits investigation of the mechanisms of tumour formation by Pu (refs 2, 3, 38) and modification of the genetic-toxicological effects of metals generally. The large variety of MLC systems available opens the way for major advances in the prophylaxis and treatment of metal toxicity, radioactive imaging with γ -emitting radiometals and diagnosis of exogenous metal body burdens by provocative or challenging doses⁴.

This work was supported largely by the US Department of Energy under contract no. EE-77-S-02-4369.A001. We thank Professors Michael P. Doyle and William S. Mungall for discussions on MLC chemistry, Jack A. Dekker for technical assistance, and Heyl & Co. for the DMPS.

Evidence that the TSH receptor acts as a mitogenic antigen in Graves' disease

GRAVES' DISEASE (GD) is an autoimmune disorder associated with the formation of thyroid antibodies, one class of which, thyroid-stimulating antibodies (TSAb), is thought to be involved in the pathogenesis¹⁻³. TSAb act similarly to thyrotropin (TSH) on the thyroid follicle cell through the mediation of adenylate cyclase⁴. The formation of TSAb is thought to be due to a change in the immune tolerance or to some alteration of the antigen, which has been suggested to be the TSH receptor². Some experimental evidence favours a defect in the immune surveillance, caused by decreased suppressor T-cell function^{2,5}. It has been reported that sensitised lymphocytes from patients with GD can produce TSAb *in vitro* after nonspecific stimulation^{6,7} as well as after specific stimulation with thyroid homogenate⁸. We report here that the lymphocyte-stimulating effect of thyroid membranes is abolished if the thyroid membranes are preincubated with TSH. According to our hypothesis, this means that the TSH receptor is the mitogenic antigen.

Eleven patients with GD and seven with toxic nodular goitre (TNG) were studied. The patients were hyperthyroid according to clinical and laboratory data (Table 1). The grouping of the patients into GD and TNG was based on clinical signs and on thyroid palpation and scintigraphy. Lymphocytes from these patients were studied with the lymphocyte transformation test. The method is described in the legend to Fig. 1. The stimulation index (SI) was calculated by dividing the mean c.p.m. of the three test cultures by the mean of the three control cultures. The mean lymphocyte SI for 10 healthy persons tested with thyroid membranes as the antigen was 1.02 ± 0.22 (mean $\pm$ s.d., range 0.61–1.35). The stimulation was considered positive when SI was more than 1.50, that is, mean + 2 s.d. In control incubations with leucoagglutinin (LA) as the mitogen, the SI varied from 20 to 90, reaching its maximum on day 3, and from 3 to 10 on day 7. SI with purified protein derivative of tuberculin (PPD) varied

Table 2 The effect of preincubation of LA and PPD with TSH

LA	Stimulation index with		
	LA + TSH	PPD	PPD + TSH
52.9	62.9	4.5	4.2
38.0	36.4	2.3	1.8
34.8	32.1	1.7	1.7
26.2	25.3	15.0	13.0
26.1	24.9		
32.0	36.8		

For further details of the lymphocyte transformation test and preincubations see the legend to Fig. 1.

from 1.7 to 15. The membranes from kidneys did not show any lymphocyte-stimulating effect in any patients tested. The coefficient of variation between triplicates was 4.1%.

When thyroid membranes were used as antigen, the mean SI was 3.64 in the patients with GD, nine of whom showed a positive response. A positive response was also seen in two patients with TNG (Table 1). Figure 1 shows the results for the 11 patients with a positive lymphocyte transformation test when leukocytes were incubated with thyroid membranes and with membranes which were preincubated with TSH. The lymphocyte stimulation disappeared completely in eight cases and partly in three. Thus, it seems that preincubation of the mitogenic membrane preparation with TSH blocked the mitogenic determinant. Preincubation of the thyroid membranes with human chorionic gonadotropin (hCG), which has the same α -subunit as TSH, failed to influence the stimulating effect of membranes (Table 1). Preincubation of LA or PPD with TSH did not substantially interfere with the mitogenic activity of either LA or PPD (Table 2).

The fact that preincubation with TSH inhibited the stimulating effect of the thyroid membranes on lymphocytes from patients with GD is considered strong evidence in favour of the hypothesis that autoimmunisation against the TSH receptor on the thyroid follicle cell membrane is the pathogenic mechanism of hyperthyroidism in Graves' disease. In other words, it seems

Table 1 Diagnosis and stimulation index in patients with Graves' disease or toxic nodular goitre

The diagnosis of hyperthyroidism was based on clinical symptoms and signs as analysed by Lamberg *et al.*¹⁴. The diagnosis was confirmed by at least one of the following tests: serum protein-bound iodine (PBI), total thyroxine (T₄), and free thyroxine index (FT₄) as calculated from T₄ and triiodothyronine uptake by Sephadex (T₃U)¹⁵. The normal values are given in parentheses under the headings. The division into toxic Graves' disease (GD) and toxic nodular goitre (TNG) was made by palpation and thyroid scintigraphy. The lymphocyte transformation test was carried out within 2 months of diagnosis. For further details of the lymphocyte transformation test see legend to Fig. 1.

that lymphocytes of patients with GD are sensitised against the patients' own TSH receptor molecule, thus inducing TSAb production. TSAb obviously cause hyperthyroidism in most patients with GD. Some patients, however, do not develop hyperthyroidism, possibly because the functional capacity of the thyroid is impaired by coexisting destructive autoimmune processes^{9,10}. Another possible reason for the lack of response is that in some patients the TSAb are merely blocking antibodies¹¹, which do not stimulate the thyroid adenylate cyclase system.

The fact that the lymphocyte transformation test was positive in only two cases with TNG indicates that this type of hyperthyroidism is not usually due to a breakdown of the immune tolerance against the TSH receptor. However, nodular goitre

and GD may coexist, as shown in studies on a long-acting thyroid stimulator¹². In the present study, one of the two cases with TNG who had a positive SI was also tested by radioreceptor method for TSAb¹³: a positive TSAb index was found.

We do not know why the self-tolerance against TSH receptors is broken, nor why GD is self-limiting. The pathogenesis of TNG is unlikely to be related to the autoimmunisation phenomena seen in GD, but nodules may exist in a GD gland.

Fig. 1 The effect of preincubation of thyroid membranes with TSH on their stimulating ability on lymphocytes from nine patients with Graves' disease (●) and two patients with toxic nodular goitre (○). *a*, Stimulation index (SI) after incubation with thyroid membranes; *b*, SI of lymphocytes from the same patients after preincubation with TSH. 40 ml of blood was defibrinated with glass beads and mixed with 6 ml of a 6% dextran (MW 110,000) solution and allowed to sediment for 1 h at 37 °C. The leukocyte-rich plasma was collected and the leukocytes were washed three times in 5 ml Hanks' balanced salt solution and suspended in Eagle's minimal essential medium (MEM) containing 100 units ml⁻¹ penicillin, 100 µg ml⁻¹ streptomycin, 2 mM L-glutamine and 10% fetal calf serum (Flow). Triplicate cultures of 1 ml containing 2×10^6 leukocytes were incubated for 7 d with or without added antigen. After 6 d incubation at 37 °C in a humidified atmosphere (5% CO₂, 95% air) 1 µCi of ¹²⁵I-labelled deoxyuridine was added to each tube. 18 h later the cells were collected on to glassfibre filter papers using a multiple automated sample collector. The filters were dried at 60 °C and counted in a gamma counter. The antigen used was a thyroid membrane preparation (10,000g)¹³ which was formalinised according to the method of Ross *et al.*¹⁶. Control experiments showed that formalinisation of the membranes did not influence their ability to bind TSH specifically. The antigen was used at a final concentration of 50 µg protein per ml of medium. The thyroid antigen was also preincubated with 500 mU TSH (Actyron, Ferring) to block the TSH receptors on membranes. Incubation was carried out for 20 min at 20 °C and used at the same concentration as the thyroid membranes alone. The control experiments with LA (Pharmacia) and PPD (State Serum Institute, Copenhagen) and the preincubations with TSH were carried out according to the same culture method. The LA concentration used was 5 µg ml⁻¹, PPD 250 IU ml⁻¹, hCG 50 IU and TSH 500 mU.

Graft-versus-host disease impairs cerebellar growth

THE mechanisms of mental retardation are of critical interest to both basic developmental neurobiologists and those in the clinical community concerned with perinatal development. The possibility of a deleterious immunological interaction between mother and fetus has long been recognised as a potential developmental hazard¹. However there have been no reports of specific conditions which involve immunological injury to the developing brain. Graft-versus-host disease (GVHD) is a model disease that can be induced naturally or experimentally by grafting mature, immunocompetent lymphoid cells into an immature, immunoincompetent host. The failure of the host, for example a newborn rat pup, to recognise the graft as non-self leads to an attack by the grafted cells on host lymphomyeloid tissues, resulting in many symptoms, including wasting, anaemia, alterations of lymphoid organ weights, hyperexcitability and an ataxic-like gait². The last two features suggest possible brain dysfunctions and have motivated our investigation of immunologically induced perinatal brain injury. The rat cerebellum was used here as a model system for the study of brain alterations during GVHD because of its well known cytoarchitecture³. In addition, its postnatal development renders it sensitive to many forms of perinatal stress^{4,5}. In this

Animals injected with either 40×10^6 Fischer lymph node cells (FLNC) or F₁ hybrid LNC were compared with non-injected littermates. DNAF/ASF is the ratio of c.p.m. per g in the DNA fraction to c.p.m. per g in the acid-soluble fraction 1 h after an i.p. injection of ^3H -TdR (2 μCi per g body weight). Results are expressed as mean $\pm$ s.e.m.

* Significantly less than non-injected controls (None), $P < 0.05$.

study, we demonstrate that significant alterations in the cerebellar cellular content and capacity for DNA synthesis occur in rats suffering from neonatally induced GVHD.

GVHD was induced by injecting 40×10^6 parental strain lymph-node cells (PSLNC) on the day of birth (day 0) into the F₁ hybrid offspring of two inbred strains of rats (Fischer and DA). Newborn F₁ hybrid animals were used because they are genetically tolerant of grafts from either parent and, thus, especially susceptible to immunological attack by parental lymphocytes. Non-injected littermates or littermates injected with harmless, syngeneic F₁ hybrid LNC were used as controls. At various ages, the pups were killed and alterations in cerebellar development assessed. First, cell acquisition was estimated by measuring total cerebellar DNA content. Second, the uptake of ^3H -thymidine (^3H -TdR) into the DNA tissue fraction from the acid-soluble tissue fraction was assessed 1 h after an intraperitoneal injection of 2 μCi per g body weight. General growth of the cerebellum was measured by determining organ weight changes and total organ RNA and protein content.

The time course of GVHD effects on cerebellar maturation is characterised by a rapid appearance of changes. Thus, at the ninth postnatal day, injected animals were relatively normal by the parameters measured here. However, at postnatal day 11 cerebellar development was noticeably altered.

As seen in Table 1, cerebellar weights were affected in animals injected with PSLNC. Between days 9 and 11 there was only a 19% increase in cerebellar weight in animals with GVHD, compared with a 26% increase in controls. Subsequent to this initial change in cerebellar weight gain, cerebella from GVHD animals remained significantly smaller than those of non-injected littermates. In addition to our assessment of GVHD effects on cerebellar weights we also weighed each intact animal, its spleen and thymus, and found weight alterations similar to those previously described in animals with neonatal GVHD⁶.

In animals injected with PSLNC, both cell proliferation and RNA and protein contents were decreased compared to either non-injected controls or controls injected with syngeneic cells. This effect was proportional to changes in cerebellar weight (Table 1).

At each day including and after day 11, there was significantly less DNA, RNA and protein, indicating a marked decrease in accretion of cell number and cellular content (Table 1). There was actually less DNA at day 14 than day 13 in cerebella from GVHD animals, possibly reflecting a degree of cell death in addition to the slowed cell proliferation. Compared to controls, the uptake of ^3H -TdR into the DNA fraction from the acid-soluble fraction was less in GVHD animals at each day

measured except day 9. Labelling of the acid-soluble fraction was not significantly different in GVHD compared to controls, but there was a great difference ($P < 0.001$) in the amount of label in the DNA fraction, suggesting that although cerebellar cells in GVHD animals can take up ^3H -TdR, the mechanism for incorporating the label into DNA is altered. It is especially noteworthy that these actions on brain growth occur at a time before body wasting is evident. Animals which received syngeneic cells, that is, lymphocytes not reactive against the host, were similar to non-injected controls with respect to either cellular acquisition or cellular content.

Histological preparations showed the regular arrangement of the layers of the cerebellum to be undisturbed in 14-d-old animals with the classic symptoms of GVHD. In addition, there was no mononuclear cellular infiltration of the cerebellum, which argues against a direct, cell-mediated attack by invading lymphocytes against cerebellar cells.

The demonstrated effects of GVHD on maturing rat cerebellum may be highly significant with respect to the development of the human cerebellum, which acquires 80% of its total neuronal cell population, that is, granule cells, during the first two postnatal years⁷. Therapeutic measures, including exchange transfusion of the immunologically immature fetus *in utero*⁸, routine transfusion of infants suffering from congenital immunological deficiency syndrome⁹, and even of lymphocytes from the maternal to the infant circulatory system¹⁰ can all place infants at risk due to the induction of a GVHD syndrome. In addition, bone marrow transplantation in children with haematological disorders can result in GVHD, and affected infants often survive mild or moderate episodes of the disease¹¹. Human infants do, in fact, receive foreign lymphocytes in these instances at a time when cerebellar cells are still proliferating, but there has been no assessment of potential CNS damage due to induction of graft-versus-host disease.

The adverse actions described here of GVHD on cell proliferation in the developing rat cerebellum indicate that the CNS is a previously unrecognised site of damage during this syndrome. The mechanism by which GVHD causes damage to cerebellar growth is still obscure. No lymphocytic invasion of the cerebellar tissue was observed in affected animals, which suggests that a blood-borne factor may be involved. Alterations in cerebellar synthetic capacity could be the result of several different agents during the course of the disease; for example, hormones like cortisone¹² or factors from activated lymphocytes such as proliferation inhibitory factor.¹³ It is conceivable that the cerebellum could be affected as an innocent bystander in a similar way to other tissues such as the skin¹⁴ and intestine¹⁵ of

animals with GVHD. Our preliminary histological studies have suggested a depletion of cells in the external germinal layer, an effect quite different from that found in malnutrition¹⁶ and some hormonal alterations¹⁷. The analysis of the process by which graft-versus-host disease selectively slows growth within the proliferative cell population in the cerebellum remains a challenge to the understanding of basic growth processes in neural development, and is under investigation in our laboratory.

Dissociation between learning and remembering in organic amnesia

IN Korsakoff's disease and certain other cases of organic amnesia there may be profound disturbance of memory with little or no other intellectual disturbance. The nature of this memory defect is controversial and in particular there is disagreement about the stage of the memory process which is impaired. There is evidence in support of three possibilities¹⁻³. Information might be inadequately acquired, maintenance of information in store might be defective or information might be inadequately retrieved from store. The results reported here suggest that inadequate acquisition is the most likely cause of the amnesia in Korsakoff's disease.

It is known that amnesic patients are inferior to controls in recognising previously seen pictures when conditions of presentation and testing are identical for both groups^{4,5}. However, when pictures are presented to Korsakoff patients for a period four to eight times longer than that given to controls, and both groups are tested 20 min later, the recognition performance of the patients is raised to that of controls⁶. We have used this effect to establish equal performance of two such groups on picture recognition after a 10 min interval and then to compare their speed of forgetting as shown by their performance after longer intervals. This obviates the difficulties that have beset previous attempts to compare the rates of forgetting of amnesic and control subjects (see ref. 7 for review).

The Korsakoff patients were seven severely amnesic males with a history of alcoholism. Four were tested at the Boston or Bedford Veterans Administration Hospitals (Massachusetts) and three were tested at the Manchester Royal Infirmary. All had a severe defect of recent memory but other cognitive

functions were intact. Their mean age was 58.4 yr and mean IQ on the WAIS scale was 104. The control group consisted of six males with no evidence of neurological or psychiatric disturbance who were ambulant inpatients on the general medical and surgical wards of the Boston VA Hospital. Their mean age was 58.8 yr and mean IQ 116.

Each subject was shown 120 slides of coloured pictures photographed from magazines (stimulus items) and asked to remember them. Recognition memory was tested 10 min, 1 d and 7 d later. In each test, a sample of 40 of the original pictures was presented, randomly interspersed with 40 new pictures (distractor items), and the subject was asked to say for each picture whether or not he had seen it previously. We aimed for 75% correct recognition by both groups after the 10 min interval. Because there was no certainty that individual subjects would achieve this level of performance after a particular exposure to the stimulus items, two sets of 240 pictures were prepared. These were all drawn from the same source and individual pictures were allocated randomly to the first or second set and, within sets, to stimulus and distractor items. The 120 stimulus items from the first set were shown to the controls for 1 s each and the range of correct responses 10 min later was 71.3-85%. The same stimulus items were presented for 4 s each to the Korsakoff patients. This enabled four of them to attain a level of performance after 10 min comparable to that of controls (78.8-83% correct). For the remaining three patients, 4 s was inadequate: their performance at this exposure was therefore treated as a calibrating experiment and was not analysed. Six hours later, these three patients were shown the second set of 120 stimulus items for 8 s each. This resulted in recognition after 10 min equal to that of the controls (72.5-80% correct). A Mann-Whitney 'U' test then confirmed that after 10 min there was no significant difference between the performance of the seven amnesic and the six control subjects ($P = 0.53$).

All subjects were tested again 1 and 7 d later, using slides from the appropriate set. The results are shown in Fig. 1. A two-way analysis of variance was carried out and this showed that the interval between exposure to stimulus items and testing (the retention interval) was the only significant source of variation ($F = 46.5$, $P < 0.001$). Neither the between-groups component nor the interaction between group and retention interval was significant. An identical pattern of results was obtained when the raw data and two kinds of transform of the data (inverse sine and logistic) were analysed. Detailed comparisons showed no significant difference between the groups for any of the three retention intervals. Furthermore, the distribution of true positive and true negative responses was virtually identical for the two groups for each retention interval (Table 1). Thus, recognition performance declines with increasing retention interval but the rate of decline does not differ between the groups. This identity of performance between the groups cannot be explained

Fig. 1 Mean % correct (TP+TN) responses (± 1 s.d.) on picture recognition test. Speed of forgetting is identical when initial performance (at 10 min) has been equated. Solid line, Korsakoff patients; dashed line, control subjects.

Table 1 Mean true positive (TP) and true negative (TN) responses on picture recognition test (maximum = 40)

	Retention interval					
	10 min		1 d		7 d	
	TP	TN	TP	TN	TP	TN
Korsakoff patients	26.7	35.6	21.1	32.0	19.4	29.4
Control subjects	28.5	34.2	24.2	31.6	20.5	29.2

by the somewhat different intelligence of the two groups for two reasons. (1) When Korsakoff patients and controls are strictly matched for IQ, their recognition performance is identical after a standard retention interval if the patients receive the stimulus for 4–8 times as long as do controls⁶. (2) In our experiment, the Korsakoff patients were on average somewhat less intelligent than the controls and therefore could not have compensated for amnesia with more intelligent strategies for learning and remembering. The performance of the Korsakoff patients was indistinguishable from that of the controls not only after 10 min (when performance of the two had been deliberately equalised) but also after the two longer intervals when any difference in the ability to remember should have become apparent. Clearly, it is not in their recognition performance that the groups differed, but in the time available to acquire information when the pictures were first presented.

The simplest interpretation of our results is that the amnesic defect of the Korsakoff patients resides in the initial learning of the information. This interpretation can be avoided only by assuming that the additional time for learning made available to Korsakoff patients resulted in their acquiring more information than the controls and losing this advantage within 10 min through defective retention or retrieval. However, such an advantage could not have been lost through faulty retention because this would require the curves to diverge after the 10 min test (Fig. 1) and the Korsakoff patients to perform abnormally poorly after the longer intervals. Nor could such an advantage be lost through greater susceptibility to interference from earlier memories—the most frequently advocated ‘retrieval theory’ of amnesia^{3,8–10}—such interference increases with retention interval¹¹ and accordingly the Korsakoff patients should forget faster than the controls. Again the curves should diverge.

It therefore seems very likely that the extra time provided for the Korsakoff patients was utilised to achieve a level of learning comparable with that which the controls achieved in less time. Accordingly, at least for picture recognition, the Korsakoff patients seem to have a defect in the initial learning of information but forget no faster than normal. Normal rates of forgetting in Korsakoff patients might seem paradoxical if organic amnesia is seen as inability to remember. However, apparent defects of retention or retrieval in these patients could in principle be—and, we suggest, are—secondary to a defect of initial learning.

Mechanism for the formation of synaptic projections in the arthropod visual system

THE axons of photoreceptors in arthropods project in a precisely ordered manner from the retina to the lamina. As retina and lamina consist of two-dimensional arrays of structural units (the ommatidia and the cartridges, respectively), a particular unit of origin and a specific target unit can be defined uniquely for each axon. In a number of species, such as water fleas¹, crabs² and locusts³, all axons originating from an ommatidium terminate in the same cartridge, where they form synapses onto laminar neurones. How is a particular target cartridge selected by the reticular axons as they grow into the laminar anlage during embryogenesis? The adult pattern of projections could arise in several ways. For example, each ommatidium and each cartridge could have unique chemical labels varying with or according to their positions in their respective domains. Input and target could then be matched by a chemoaffinity mechanism such as that originally proposed by Sperry⁴ for the formation of vertebrate retinotectal connections. A second possibility is that reticular fibres do not recognise any specific labels in the laminar cells, but grow into this region in the appropriate spatio-temporal order to sequentially fill available sites in a pre-formed laminar array. In a variation of this second mechanism the lamina would be unstructured at the time of arrival of reticular axons and the axons would impose a pattern on the lamina by sequentially recruiting immature laminar neurones to form the regular array of cartridges. These possibilities have been tested by deleting ommatidia at specified developmental stages in *Daphnia magna*, a small branchiopod crustacean with a total of 22 ommatidia and 22 cartridges¹. The observations reported here support the last hypothesis, that the order of reticular axon ingrowth determines the retino-laminar projections in this organism.

The formation of the retino-laminar projection in *Daphnia* follows a precise sequence of events which occurs during the middle stages of embryogenesis^{5,6}. This is shown schematically in Fig. 1. Reticular axonal bundles arrive in order at the midline of the laminar anlage, where they contact immature laminar neurones with which they will subsequently form cartridges and move away from the midline. In order to determine whether a bundle of reticular fibres only interacts with a specific, pre-determined group of cells, I used a UV radiation microbeam to delete ommatidia during development before their axons made such contacts. Two possible outcomes of such an experiment are shown schematically in Fig. 2. On the left, cartridges which normally correspond to the deleted ommatidia receive no reticular projections; on the right, the last cartridges that would form are the affected ones.

Lesions were made in about 40 embryos at different locations in the eye anlage, deleting 1–10 ommatidia before their fibres grew into the lamina⁷. Animals were fixed at various times after the irradiation and serially sectioned for light or electron microscopy. The analysis was in part performed with the aid of three-dimensional computer reconstructions from these sections⁸.

Some data on experimental animals analysed as adults are presented in Table 1. For every ommatidium which was completely removed in the embryo, five laminar neurones, and

Fig. 1 Schematic diagram of a rostro-caudal cross-section of two *Daphnia* embryos; left, 30 h old; right, 33 h old. Only the eye and lamina on the right of the midline are shown. A–D, Ommatidia; a, b, cartridges. ML, midline; AN, available immature neurones. The photoreceptors in ommatidium A are the first to differentiate. They send processes along the midline into the lamina, where they encounter laminar cells without processes. Within each future ommatidium one cell matures earlier than the other seven; its growing fibre precedes or ‘leads’ the other seven into the lamina. The lead fibre sequentially contacts five laminar cells which then wrap around this fibre and form transient gap junctions with it^{5,6}. The cells which are contacted are always those closest to the anterior surface and the midline of the laminar anlage. As the following fibres of the bundle arrive, the laminar cells unwrap partially, form a ring around the bundle and elaborate processes which grow in parallel with the receptor fibres into the forming neuropil. After cartridge a is formed in the lamina, it moves laterally as the fibres from ommatidium B arrive. After cartridge b is formed, it also moves laterally behind cartridge a. The fibres from ommatidium C then arrive at the midline and contact five immature neurones. At 33 h, the first cartridges to form have begun to elaborate processes which grow into the future neuropil region. Synapses will appear a few hours later.

hence a cartridge, were missing in the adult. When an ommatidium was only partially deleted, however, a smaller than normal cartridge was formed. From these data it was not possible to determine conclusively which one of the cartridges was missing when an ommatidium was removed. In no case out of 17 analysed in detail were there found any areas filled by glia but devoid of neurones, or any groups of degenerating laminar neurones that would allow identification of the missing cartridges. In each case the cross-sectional area of the lamina was reduced in proportion to the number of missing structures. (It has also been shown that eye deletions strongly affect laminar structure by genetic manipulation in *Drosophila*⁹ and surgical manipulation in other species^{10,11}.)

Table 1 Numbers of reticular neurones, ommatidia, laminar neurones and cartridges in animals irradiated as early embryos and analysed as adults using 3-D computer reconstructions from serial sections

Specimen	No. of reticular neurones	No. of ommatidia*	No. of laminar neurones	No. of cartridges*
A	163	20	99	20
B	153	20	94	20
C	116	18	87	18
D	87	14	68	14
E	89	12	57	12
F	127	16	79	16
Control	176	22	110	22

* Some ommatidia and their associated cartridges have fewer than the normal complement of neurones (8 and 5, respectively) in experimental animals

Two observations on experimental animals analysed at embryonic stages ranging from 3 to 20 h after irradiation showed that the cartridges which degenerate are the last ones to form. First, immature laminar neurones, including those that later disappear, are still to be found within the laminar anlage until some hours after all reticular fibres normally arrive at the lamina. No signs of laminar cell degeneration are found until some 10–12 h after the 38 h stage, when the last bundles grow into the lamina (see Fig. 3). Second, no group of laminar neurones without an associated bundle of reticular fibres is found away from the midline at any stage during or after the arrival of the reticular bundles. In other words, at no developmental time is there a situation like that shown in Fig. 2 (left). Instead, laminar cells that are not contacted because of the reduced number of reticular bundles are found near the midline, as diagrammed in Fig. 2 (right) (see also Fig. 3). These left-over cells fail to elaborate fibres at the time when corresponding normal groups, located symmetrically about the midline, are well differentiated.

The extra laminar cells could, in principle, be either the last group to appear, group d in Fig. 2, or group b which, as it was never contacted because ommatidium B was deleted, has remained near the midline. My observations of the temporal pattern of fibre ingrowth and of the geometry of the laminar anlage support the first alternative. The immature neurones contacted by a growing fibre bundle are always those closest to the anterior surface and the midline. Therefore, if growing bundle C is to contact laminar group c, then group b must be displaced away from the midline. Yet a group of laminar cells is never observed away from the midline without an associated reticular fibre bundle. It is conceivable, though rather unlikely because of the geometry of the developing lamina, that groups b and c permute positions if b is not contacted at a specific time. However, in no experimental animal studied at the appropriate embryonic stage was there any indication that laminar cells move from the anterior surface back toward the more posterior regions from which they originally arise. Though I cannot absolutely dismiss the possibility that group b recycles back to

Fig. 2 Two possible outcomes of the deletion of ommatidium B. (Nomenclature as in Fig. 1.) Left, if ommatidium C recognises and contacts only the laminar cells which will form cartridge c, then we should find, at some developmental stage, a group of neurones in the b position which do not receive a reticular projection. Right, if the fibres from ommatidium C recruit whatever laminar cells are available, they will contact those cells that will normally become cartridge b. The deletion of ommatidium B then would lead to the d laminar cells remaining untouched and available.

Fig. 3 Low power electron micrograph of a rostro-caudal section from a set of serial sections of an embryo irradiated on the right side at 31 h and fixed at 50 h. M, midline; LR and RR, left and right retina; LL and RL, left and right lamina; C, cartridge; B, fibre bundle travelling from LR to LL. The corresponding fibre bundle on the right was deleted by irradiation. Arrows indicate debris from degenerating cells which has been internalised by glial cell g. Immature neurones, n, that remain without an associated reticular bundle are found at this stage only on the right side of the midline. Computer reconstructions from the serial micrographs show that these immature neurones have failed to elaborate processes, unlike the neurones in corresponding positions on the left side of the midline. Note that, because of these left-over cells, cartridge C on the right is more distant from the midline than the one on the left. $\times 2,400$.

the surface region where the left-over cells are found, I believe from my observation of the temporal sequence of events that it is highly unlikely. I conclude that the extra cells are the last to arrive, that is, those that normally would have become part of the cartridge d.

From these observations the following developmental scheme in the *Daphnia* visual system can be formulated. As reticular fibres arrive at the laminar anlage they recruit whatever immature laminar neurones are available at that time and in that position. (This recruitment process could be mediated by signals exchanged during the early, characteristic interaction between reticular fibres and immature neurones which have been described previously⁶.) The order of synaptic projections is a consequence of the spatio-temporal sequence of ingrowth of optic fibres and no special affinity of ommatidia for specific targets is required. In animals with retinal lesions the extra laminar cells fail to differentiate because they do not receive a required signal from reticular fibres. The degeneration of laminar cells deprived of contacts provides evidence supporting cell death as the mechanism for regulating relative numbers of neurones in this system. Such a regulatory role for cell death has been previously suggested in both invertebrate¹² and vertebrate nervous systems¹³.

In conclusion, experimental evidence has been obtained which indicates that, in a structure whose parts normally mature in a spatially and temporally ordered fashion, neurones and their targets need not be individually labelled in order for appropriate synaptic projections to be achieved. Horridge³ arrived at a similar conclusion when he observed normal optokinetic responses by locusts that had regenerated eye-lamina connections following eye rotation at the second instar larval stage. However, as about two-thirds of the retina is added at later instars¹¹, it is unclear whether this result is due to normal development of the remaining retina following the graft rotation or to the regeneration of connections from the existing ommatidia. A spatio-temporal mechanism has also been suggested by Gottlieb and Cowan¹⁴ as a possible way to account for the

genesis of the pattern of synaptic connections in the dentate gyrus of the rat. In those cases where all fibres grow in and form synapses simultaneously, however, a different mechanism, such as chemoaffinity⁴ or fibre-sorting¹⁵, might be necessary.

Although sequential differentiation of photoreceptors also takes place in *Drosophila* and other insects (see ref. 16 for review), the details of the developmental interactions are not known in these species. My results on *Daphnia*, and parallels in the developmental process in various species¹⁶, suggest that mechanisms involving cell-cell contact as the signal for specific recruitment and differentiation of target cells may be generally valid in the formation of the retino-laminar system of invertebrates.

I thank E. Holtzman, E. Kandel, C. Levinthal and R. Schehr for reading the manuscript. This research was supported by NIH grants NS117338 and NS09821. The computer work was performed at the Biology Computer Graphics Facility, which is supported by NIH grant RR00442.

Phase-locking in goldfish saccular nerve fibres accounts for frequency discrimination capacities

THE auditory systems of fishes have been of particular interest in the development of auditory theory because a mechanical analysis of frequency had seemed unlikely on the basis of the ear's rather undifferentiated structural organisation¹. Thus, at the level of the 8th nerve, information about stimulus frequency is thought to be coded in the temporal structure of neural activity rather than in across-fibre distributions of impulse rate²⁻⁴. However, recent neurophysiological data show that a limited peripheral frequency analysis occurs in several species⁵⁻⁷ and some workers have suggested that this may form the basis for psychophysical demonstrations of filtering⁸⁻¹⁰ and for frequency discrimination in the fish auditory system^{11,12}. Such a 'place principle' of frequency analysis and pitch perception is presently generally believed to originate in the phyletic series among the amphibia and to reach the greatest degree of elaboration with the mammals¹³. We report here an experiment which helps to resolve this question of frequency codings by evaluating the adequacy of the temporal hypothesis to account for the behaviourally measured frequency difference limens for the goldfish^{11,12}. A simple form of the temporal coding hypothesis states that the reciprocal of stimulus frequency (period) is

represented in 8th nerve fibres as the distribution of time intervals between phase-locked impulses⁴. A discrimination between two different period lengths may thus entail a decision as to whether the two resulting distributions of neural interspike intervals are the same or different. Clearly, the performance on such a discrimination would be limited by the variability of the distributions, or the accuracy with which neural impulses are phase-locked to the stimulating waveform. We demonstrate here that the neurones which phase-lock best at any given frequency show degrees of phase-locking accuracy that would be expected if the central nervous system were processing the input optimally.

The details of the method used for the neurophysiological measurements have been published previously⁷. Phase-locking variability of single saccular neurones of the goldfish was measured in response to tones presented at the frequencies and amplitudes used in behavioural measurements of frequency discrimination¹¹. Extracellular potentials were recorded from single saccular nerve fibres in 15-cm common goldfish, anaesthetised (MS-222) and immobilised (Flaxedil). Generally, saccular neurones could be classified into high frequency (HF) and low frequency (LF) types. The LF neurones showed best frequencies below 200 Hz, whereas the HF type showed best frequencies ranging between 300 and 800 Hz. Highly spontaneously active neurones showed little adaptation and were stimulated with continuous tones of up to 10 s duration. Neurones with little or no spontaneous activity showed rapid adaptation and were stimulated with 100-ms tone bursts, repeated at 2 Hz.

Neurones could be 'held' from seconds to over an hour, with the LF type usually lasting longer and exhibiting larger spikes (5–40 mV) than the HF type (0.5–20 mV). When a neurone was encountered, it was stimulated with a set of frequencies at sound pressure levels 35 dB above behavioural threshold¹⁴ until it was 'lost' or until the stimulus set was exhausted. For each signal, a 10-min period histogram¹⁵ was obtained from which measures of phase-locking variability were made. Figure 1 shows the period histograms obtained for four representative neurones

Fig. 1 Period histograms for four representative neurones, 204(a), 205(b), 209(c) and 216(d), from one animal for 1 s of sinusoidal stimulation at the frequencies indicated. Sound pressure levels are 35 dB above behavioural threshold¹⁴. The number associated with each histogram is the standard deviation of the distribution in ms.

Fig. 2 The standard deviations (in ms) of period histograms for 45 high-frequency neurones (■) and 22 low-frequency neurones (●) to sinusoidal stimulation at 35 dB above behavioural threshold¹⁴ from nine animals. The line connects the mean just-noticeable differences in stimulus period (in ms) measured psychophysically for four animals in a previous study¹¹.

from a single animal. From each histogram, average discharge rate, the location of the mean (phase angle) and the coefficient of synchronisation (R) were calculated¹⁶. The coefficient R was then transformed into a standard deviation value in ms (ref. 17). These values are plotted as a function of frequency in Fig. 2 for 63 of the most sensitive neurones encountered in this study (nine animals). Also plotted in Fig. 2 are the mean just-discriminable differences in period length (ΔP) for four goldfish tested in similar stimulus conditions in a previous study¹¹. The behavioural ΔP values generally fall within the range of the smallest period histogram standard deviation values obtained at each frequency.

A simple temporal coding hypothesis holds that stimulus period lengths are estimated by the measurement of the temporal intervals between nerve impulses¹⁸. The discrimination problem may be viewed as a decision as to whether two samples of neural interspike intervals are drawn from the same, or two different underlying distributions. Assuming that the means of these hypothetical distributions are equal to the periods of the two signals to be discriminated, and that the distributions' variance is completely determined by the phase-locking variance, then we would expect threshold-like behaviour to occur when the difference between the means (ΔP) is approximately equal to the distributions' standard deviation (sd), that is, when $d' = \Delta P/sd = 1$ (ref. 19). The results show that this is indeed the case for the smallest sd values at each of the frequencies studied. Thus, peripheral phase-locking variance accounts well for the errors made in behavioural frequency discrimination, with the assumption that the decisions are based on the small percentage of neurones transmitting the best information.

A similar analysis was carried out by Mountcastle *et al.*¹⁸ for cutaneous flutter vibration discrimination. Human vibratory frequency discrimination performance was compared with the standard deviations of period histograms for somatosensory cortical neurones in the monkey. For vibratory frequencies between 5 and 200 Hz, the behavioural estimates of the *sds* of the underlying sensory distributions fell within the range of the smallest neural *sds*. These results for the cutaneous system are also similar to the present results in that both neural and behavioural measures of error decline approximately linearly with frequency (with unity slope in log-log coordinates), and in that the actual values of the cutaneous *sds* are only about twice as large as those of the goldfish auditory system.

Although the present results show that a simple temporal coding hypothesis accounts quite well for the behavioural capacities for frequency discrimination in the goldfish, possible alternative hypotheses are not ruled out. Further experiments are required in which phase-locking variance may be manipulated; for example, through the introduction of temporal 'jitter' in the stimulus waveform, or through the use of aperiodic stimuli such as amplitude-modulated noise²⁰. The nature of central neural mechanisms which decode the temporal input patterns remains to be explored. The goldfish seems to be a valuable preparation for combined behavioural and neurophysiological approaches to the coding of temporal patterns by nervous systems.

Sinus node extracellular potassium transients following vagal stimulation

SEVERAL investigations have suggested a role for K^+ in the generation of the transmembrane potential during spontaneous rhythm^{1,2} and following vagal inhibition^{3,4} of the sinoatrial node (SA node) of the heart⁵. Voltage-clamp studies^{1,2} in the rabbit SA node have shown a voltage- and time-dependent increase in the outward current on depolarisation and a slow decay of the outward current on repolarisation to the holding potential. The hyperpolarisation and slowing of automaticity following vagal stimulation or acetylcholine (ACh) application is believed to be due to an increase in potassium permeability^{3,4}. The purpose of the present study was to use K^+ -sensitive microelectrodes^{6,7} to examine the time course and the magnitude of K^+ efflux and

Fig. 1 *a*, The response of both barrels of a double-barrelled K^+ -sensitive microelectrode to skewed sine-wave calibrating pulses of similar time course and magnitude to extracellularly measured action potentials. Selective barrel, $V_K + V_O$; reference barrel, V_O . V_K represents the differential output showing common mode rejection at this level of resolution. *b*, The output of both barrels with the double-barrelled K^+ -sensitive microelectrode in the extracellular space of the SA node. Selective barrel, $V_K + V_O$; reference barrel, V_O . The differential trace, V_K , now shows periodic fluctuations with the same periodicity as the crista terminalis electrogram (CT) and extracellular potential fluctuations (V_O). V_K represents beat-to-beat alterations in $[K^+]_o$ and is uncontaminated by common mode rejection artefacts (see *a* above). In the V_K record 0.2 mV is equivalent to 0.034 mM potassium.

extracellular accumulation in the isolated rabbit SA node during spontaneous rhythm and following vagal stimulation. Our results confirm that K^+ permeability of the sinoatrial pacemaker cell is increased following vagal stimulation and demonstrate K^+ accumulation in the extracellular space for several seconds. Beat-to-beat extracellular potassium transients are linked to the repolarisation process as well as to diastolic depolarisation.

Experiments were carried out on rabbits (1-3 kg) anaesthetised with 10 mg per kg intravenous sodium pentobarbital. The hearts were removed and placed in Tyrode's solution, gassed with 95% oxygen and 5% CO_2 , and maintained at 37 °C; 1.0 mg l^{-1} propranolol was added to the Tyrode's to eliminate β -adrenergic influences. The atrium was opened according to the dissection of Paes de Carvalho⁸. Vagal stimulation was accomplished by a previously described⁹ modification of the technique of Vincenzi and West¹⁰. Bipolar silver electrodes were placed on the endothelial surface of the superior vena cava in the region traversed by vagal fibres innervating the sinus node area¹¹. The vagal stimuli were delivered as a train of 4-ms square-wave pulses at 100 Hz for 100-300 ms. Silver bipolar electrodes were used to record from the surface of the crista terminalis (CT) and right atrial muscle. Standard 3 M KCl-filled microelectrodes were used to record transmembrane potentials from sinus node fibres.

Double-barrelled K^+ -sensitive microelectrodes were prepared by filling the tip of one barrel of a double-barrelled glass micropipette, pretreated with a siliconising agent, with K^+ -selective resin (Corning liquid resin no. 477317 with $K^+ : Na^+$ selectivity of approximately 60:1) (refs 6, 12). The selective barrel was then backfilled to the top of the resin column with 100 mM KCl. The other barrel was backfilled with normal Tyrode's solution. K^+ electrodes with tips of 3-4 μm had a resistance of about 1,000 M Ω and an electrical response time of 15-20 ms. The chemical response time of the electrode to variation of K^+ was found to be faster¹². Selectivity values were measured before and after experiments with a series of calibrating solutions with potassium concentrations (mM) of 2.7, 10, 20, 50 and 100. Signals from the K^+ -selective barrel and the reference barrel were independently amplified by high-input impedance amplifiers ($1.5 \times 10^{12} \Omega$) with capacitance compensation. The amplified signals were differentially subtracted by a third amplifier (Bloom). Thus, we were able to obtain the potassium potential (V_K) free of the extracellular potential (V_O) fluctuations which were common to both barrels (Fig. 1*a*).

Records were simultaneously displayed on a Tektronix 5103 oscilloscope and stored on an eight-channel Hewlett Packard instrumentation tape recorder 3968A.

During advancement of the K^+ electrode into the extracellular space of the SA node, occasional large transient positive deflections on the K^+ barrel were seen. These were probably the result of the electrode rupturing cell membranes and exposing the electrode tip to the high intracellular potassium concentration. Action potentials were occasionally recorded with the double-barrelled electrode. The K^+ electrode was manipulated and either pulled back or advanced through the cell until a location was found where potential fluctuations common to both barrels were less than 10 mV. Time was allowed for elevated extracellular potassium values associated with membrane rupture to stabilise to values which corresponded to the approximate value of K^+ in the perfusate (2.7 mM).

At many of these K^+ electrode positions, beat-to-beat fluctuations in extracellular potassium were recorded (Fig. 1b). These fluctuations had the same periodicity as the spontaneous rhythm as determined by the intracellular SAN recordings and the CT electrogram (Fig. 2). The extracellular potassium concentration ($[K^+]_o$) increased gradually during phase 0 depolarisation, reaching a peak change in concentration of approximately 0.05 mM which corresponded to the middle of phase 3 repolarisation. It then subsided rapidly during the last half of phase 3 repolarisation, and the beginning of phase 4 diastolic depolarisation. There was a slower decay of potassium concentration throughout phase 4 diastolic depolarisation. The maximum peak change in K^+ concentration fluctuation in these extracellular measurements was 0.07 mM.

While continuing to monitor beat-to-beat extracellular K^+ fluctuations, vagal stimulation was applied. This was accompanied by characteristic changes in the intracellular potential response of the SA node. Initially, there was a hyperpolarisation of the maximum resting membrane potential, a decrease in the slope of diastolic depolarisation and a shortening of the action potential duration. Simultaneous $[K^+]_o$ measurements following vagal stimulation showed elevations of extracellular K^+ in the SA node of up to 0.2 mM. Following the peak accumulation, $[K^+]_o$ returned to baseline over a period of 8–13 s (Fig. 3). In some cases, $[K^+]_o$ values fell below previous baseline activity before returning to its original resting level. This potassium undershoot has previously been described by Kunze after a

period of rapid pacing in atrial muscle¹³ and by Kriz *et al.* in cat spinal cord after peripheral tetanic stimulation¹⁴. Both authors suggest that this subnormal phase of $[K^+]_o$ reflects active processes redistributing K^+ from the extracellular space.

Because of the large amount of connective tissue in the SA node^{1,2,15}, beat-to-beat fluctuations were not seen for all electrode locations⁷. In addition, in some locations where a vagus-induced $[K^+]_o$ increase is seen, beat-to-beat fluctuations are either small or below the resolution of our electrode. Furthermore, it is known that cells in the mammalian SA node are tightly packed⁵; at the point of apposition of two cellular membranes, the extracellular space takes the form of 100–150-Å-wide intercellular clefts¹⁶. The tip of the double-barrelled K^+ electrode is approximately 3–4 μ m outside diameter. Therefore, the K^+ electrode tip must rest in an artificially distorted dead space¹⁷. Thus, the efflux into the extracellular space where the electrode tip rests is substantially diluted compared with the normal cleft space. For a prolonged change in the extracellular K^+ activity of the tissue, the dead space would equilibrate with the normal extracellular concentration. However, for short-term fluctuations of K^+ activity in the intercellular cleft, the response measured by the K^+ electrode would be considerably smaller than the actual intercellular changes.

Fig. 3 Accumulation of potassium in the extracellular space of the sinoatrial node after vagal stimulation measured by a double-barrelled K^+ -sensitive microelectrode. CT, bipolar surface electrogram of the crista terminalis. SAN, transmembrane potential recording from sinus node fibre. Following vagal stimulation (VS), note the hyperpolarisation of the maximum resting membrane potential, decrease in the slope of diastolic depolarisation and shortening of the action potential duration. These events are coincident with the accumulation of K^+ in the extracellular space (V_K). Zero transmembrane potential is indicated by the upper edge of the bracket of the top calibration. 2.7 mM $[K^+]_o$ is indicated by the lower edge of the bracket of the bottom calibration.

Fig. 2 Beat-to-beat extracellular potassium concentration fluctuations in the rabbit SA node during spontaneous activity measured by a double-barrelled K^+ -sensitive microelectrode. Bipolar surface electrogram of the crista terminalis at an area shown to be activated earliest during spontaneous sino-atrial conduction (CT). Transmembrane potential recording from sinus node fibre (SAN). Simultaneous potassium response was measured by subtraction of the reference barrel from the K^+ -selective barrel (V_K). As the reference barrel has been used to compensate for the electrical artefacts in the extracellular space, V_K represents the response of the K^+ -selective barrel only to changes in the K^+ concentration. The K^+ electrode is nearly linear in its response to $[K^+]_o$ for small accumulations seen during single action potentials. Zero transmembrane potential is indicated by the upper edge of the bracket of the top calibration. 2.7 mM $[K^+]_o$ is indicated by the lower edge of the bracket of the bottom calibration.

In the normal physiological range of extracellular potassium concentration, potassium-sensitive electrodes have been reported to show sensitivity to Ach fluctuations. (1 mM increase in K^+ is equivalent to the addition of 5×10^{-7} M Ach; see ref. 18.) To determine whether vagally induced release of Ach was affecting the K^+ electrode response, we added atropine to our experimental perfusate (0.2 to 1 mg l⁻¹). Atropine blocks the post-synaptic effect of Ach but not its release. We saw no vagally induced K^+ electrode response in the presence of atropine at concentrations sufficient to eliminate vagally induced rate responses. However, beat-to-beat K^+ changes were still observed.

Thus, we have confirmed the belief that the potassium permeability of the SA node pacemaker cell is increased following vagal stimulation. Extracellular potassium accumulation associated with vagal stimulation persists for several seconds and one must consider the possibility that this may contribute to membrane potential and rhythm changes after this intervention. Our direct measurement of beat-to-beat extracellular K^+ changes support the previously described observations made from voltage-clamp experiments. Beat-to-beat $[K^+]_o$ transients seem to be linked to the repolarisation process as well as to the automatic phase 4 diastolic depolarisation of the sino-auricular node of the isolated rabbit heart. This technique may thus be useful in studying the behaviour and reaction of the K^+ currents of the SA node in various conditions.

Immunochemical demonstration of reversible reduction in choline acetyltransferase concentration in rat hypoglossal nucleus after hypoglossal nerve transection

STUDIES of the cellular reaction of peripheral and central catecholaminergic neurones to axonal injury (the retrograde reaction and axon response) have demonstrated that such lesions elicit a prolonged reduction within the parent cell body in the activities and amounts of the catecholamine biosynthetic enzymes tyrosine hydroxylase (TH) and, in noradrenergic neurones, dopamine- β -hydroxylase (DBH)¹⁻³. The reduction in enzyme protein, usually reversible, lasts for several weeks and is apparently due to a decrease in the rate of enzyme biosynthesis⁴. It has therefore been proposed that a reduction in amount and activity of neurotransmitter biosynthetic enzymes may be a biochemical indicator of the retrograde reaction⁵. However, it remains to be established if a reversible diminution of neurotransmitter biosynthetic enzyme occurs during the retrograde reaction in neurones which synthesise neurotransmitters other than catecholamines. This is suggested from studies of the retrograde reaction in hypoglossal neurones, cholinergic motor neurones which innervate the tongue through the hypoglossal nerve. During the retrograde reaction elicited by lesions of the hypoglossal nerve, the activities of choline acetyltransferase (CAT), the enzyme synthesising acetylcholine, and acetylcholinesterase (AChE), the enzyme degrading it, are markedly reduced⁵⁻⁷. If the proximal stump of the lesioned nerve is allowed to regenerate and reestablish synaptic contact, AChE activity within the hypoglossal nucleus rapidly reappears⁷. It is, however, unknown whether the reduction in CAT activity is reversible and, because of a lack of specific, inhibiting antibody to CAT, whether the reduction is due to a decrease of enzyme molecules. We report here that the reduction in CAT in hypoglossal neurones elicited by transection of the hypoglossal nerve

is reversible and also, by use of a specific antibody, that it is due to a decrease in the amount of CAT enzyme protein.

All studies were carried out on adult, male Sprague-Dawley rats weighing 175-225 g. While the animals were anaesthetised with 3% fluothane in 100% O₂ blown over the nose, the hypoglossal nerve was isolated unilaterally, distal to the cricoid cartilage and the major bifurcation of the nerve. A 2-3-mm segment was excised, with special care taken to include both branches. At various days after surgery the animals were killed by cervical dislocation, and the brain was removed and dissected on cracked ice. The right and left hypoglossal nuclei were removed as a block which included parts of the dorsal motor nucleus of the vagus and the nucleus tractus solitarius, and homogenised in 50 mM potassium phosphate buffer, pH 6.8, containing 1 mM sodium EDTA, 200 mM sodium chloride and 0.4% v/v Triton X-100. CAT was assayed by the radiochemical method of Schrier and Shuster⁸, and AChE was assayed by the method of Wilson *et al.*⁹. The identity of the cholinesterase activity as true acetylcholinesterase was confirmed by the observation of 90% inhibition of cholinesterase activity by 2×10^{-7} M BW 284 C51, a specific inhibitor of true acetylcholinesterase.

Antibodies to CAT were prepared by methods described in detail elsewhere^{10,11}. In summary, the enzyme was isolated from rat caudate nuclei and first partially purified by Sepharose 4B and DEAE-cellulose column chromatography, then subjected to polyacrylamide gel electrophoresis. The single active protein band was cut from the gel, suspended in 0.9% NaCl solution, thoroughly mixed with complete Freund's adjuvant, and injected subcutaneously into rabbits every 2 weeks for a total of four treatments. The serum was collected one week after the last injection. The antibody to CAT was adjudged specific by immunoelectrophoresis against crude and partially purified CAT from rat caudate nucleus and that the antibody inhibited only the activity of CAT in purified form or in brain homogenates.

Fig. 1 Time course of changes in activities of CAT (closed circles) and AChE (open circles) in the ipsilateral hypoglossal nucleus following unilateral lesion of the hypoglossal nerve. Enzyme activity is expressed as % of mean activity in the contralateral control hypoglossal nucleus. Neither the activities of AChE nor CAT changed in the control hypoglossal nucleus throughout the time course studied. Each point represents the mean $\pm$ s.e.m. of 6-8 animals. The specific activities of CAT and AChE in the left and right hypoglossal nuclei of control (unoperated) rats were as follows: CAT (left/right), $80 \pm 7/74 \pm 7$ nM per mg protein per 10 min; AChE (left/right) $1.9 \pm 0.1/1.9 \pm 0.1$ μ M per mg protein per 10 min.

Immunotitration was carried out by adding increasing amounts of antiserum to CAT to 80- μ l aliquots of appropriately diluted supernatants of rat hypoglossal nucleus homogenates. Aliquots of 1:1 preimmune serum diluted with distilled water were added to each sample to bring the final volume to 90 μ l. The mixture was then agitated and allowed to stand for 1 h at room temperature with occasional shaking, incubated overnight at 4 °C, and centrifuged at 9,150g for 10 min. A 75- μ l aliquot of the supernatant was removed for assay of residual CAT activity.

Other rats subjected to hypoglossal nerve lesion were perfused with 10% formalin, the brains were removed, further fixed in Bouin's solution and embedded in paraffin. Ten- μ m sections were made through the hypoglossal nucleus, stained with cresyl violet and then examined by light microscopy.

Figure 1 shows changes in the activity of CAT in the hypoglossal nucleus at different days after hypoglossal nerve section. No change was observed after 24 h, but by 3 d the activity had fallen to 50% of control. Five weeks after the lesion, activity had returned to control levels. CAT activity did not change in the contralateral hypoglossal nucleus. Hypoglossal nerve section also produced reversible changes in AChE activity, similar in time course to but smaller than that of CAT (Fig. 1), confirming, in part, the findings of others^{6,7}.

To determine whether the transient reduction in CAT activity in the hypoglossal nucleus after hypoglossal nerve section was due to a decrease in specific enzyme protein or to an inactivation of pre-existent enzyme molecules, the degree of inhibition by antibody to CAT activity in homogenates of control hypoglossal nuclei was compared with that of nuclei whose hypoglossal nerve had been sectioned 7 d previously. The results of a typical experiment are shown in Fig. 2. As increasing amounts of antiserum were added to a fixed quantity of homogenate, CAT activity in the supernatant decreased. The slopes and equivalence points (that is, that quantity of antibody which just saturates the available antigen) of immunotitration curves for both experimental and control hypoglossal nuclei were quite similar. These results indicate that the reduction in CAT activity in the hypoglossal nucleus following hypoglossal nerve section is due to a reduction in the concentration of enzyme protein.

During the retrograde reaction, minimal changes of chromatolysis were observed in the affected hypoglossal nucleus. These changes consisted of a slight increase in nucleolar size and darkening of chromatin. No loss of neurones was noted based on careful counts of neurones in randomly selected sections through the nucleus.

The present study shows that the reduction in CAT activity in the hypoglossal nucleus during the retrograde reaction is entirely reversible. The immunotitration studies demonstrate that the reduction in perikaryonal CAT activity following hypoglossal nerve lesion is a result of a diminution in the quantity of CAT protein rather than inactivation of the enzyme. This reversible reduction in enzyme protein may be due to either a reduction in CAT synthesis or an increase in the rate of degradation of the enzyme. The observation that the reversible reduction in DBH which occurs in central noradrenergic neurones is entirely due to a diminished rate of synthesis⁴ suggests a reduction of synthesis of this specific protein. It is intriguing that the time courses of the reversible reductions in AChE and CAT activities in the hypoglossal nucleus following axotomy are so similar. Many studies suggest that AChE is transported along the axon at a very rapid rate, whereas CAT is transported at a predominantly slow rate⁵. Despite these apparent differences in axonal transport rates, our data suggest that the two enzymes may have similar control mechanisms in the cell body.

Thus, like noradrenergic neurones arising in the locus coeruleus³, and central dopaminergic neurones⁸, injury to axons of the hypoglossal nerve, a cholinergic motor nerve, results in a reversible reduction in the capacity of the neurone to accumulate the enzyme which catalyses the biosynthesis of the neurotransmitter as well as the one degrading it. However, others have shown that in the hypoglossal nucleus during the period of

Fig. 2 Immunochemical titration of choline acetyltransferase in the hypoglossal nucleus from control (open circles) and experimental (closed circles) rats. The hypoglossal nerve ipsilateral to the experimental hypoglossal nucleus had been sectioned 7 d earlier. The homogenate of the control nucleus was diluted 1:2 so that the enzyme activity per unit volume was approximately equal in the experimental and control preparations. Note that the slopes and equivalence points are nearly identical. Linear regression analysis of each curve produced the following equations: control, $y = -0.065x + 0.621$; experimental, $y = -0.066x + 0.553$.

reduction in AChE and CAT activities there is an increase in the rate of incorporation of labelled amino acid into protein¹³ as well as an increase in the total protein content per cell¹⁴. Thus, the reduction in neurotransmitter-metabolising enzymes in cholinergic cell bodies is probably highly selective, involving a very small percentage of the total amount of protein synthesised in the cell body. These results and those of previous studies on central catecholaminergic neurones suggest that a reversible reduction in transmitter-synthesising capacity in the cell body may be a sensitive and specific indicator of axonal damage. It seems likely that during the 2–4-week period following axotomy the first priority of the neurone is to regenerate its axons and in the case of peripheral neurones like the hypoglossal, to re-establish synaptic contacts. During this recovery phase, protein synthesis associated with regeneration seems to establish priority over protein synthesis subserving neurotransmission.

Membrane specialisations between demyelinated axons and astroglia in chronic EAE lesions and multiple sclerosis plaques

AXOLEMMAL specialisations are known to exist along myelinated fibres in the adult vertebrate central nervous system (CNS), particularly at nodes, between the axon and the oligodendrocyte, and at presynaptic sites¹. However, modified regions of axonal membrane have not been described in relation to astroglial cells. In demyelinated lesions in the CNS, it has always been assumed that the naked segment of an axon, although intimately invested by glial scar tissue, shares no junctional relationships with its scarring environment. This report documents for the first time membrane specialisations between naked CNS axons and fibrous astroglial cell processes, developing subsequent to demyelination. These structures may have physiological implications.

Spinal cord tissue from two demyelinating conditions have been examined. First, from strain 13 guinea pigs affected with chronic relapsing experimental allergic encephalomyelitis (EAE)², and second, from a case of chronic multiple sclerosis (MS), the paradigm of the human CNS demyelinating diseases³.

Chronic relapsing EAE was induced by sensitisation of juvenile strain 13 guinea pigs with isogeneic spinal cord tissue in complete Freund's adjuvant². Typically, animals developed delayed onset neurological signs (incontinence, paraparesis, and

so on) some 8–12 weeks post-inoculation (PI). These signs remitted, albeit incompletely, and were usually followed by several relapses. This clinical course is highly reminiscent of that of MS, for which the disease serves as a major experimental analogue. In the present study, five animals have been studied. One was sampled at the first onset of signs (10 weeks PI), three after a single relapse (12–24 weeks PI), and one after two relapses (20 weeks PI). Slices of spinal cord from L₆, L₇ and S₁ were obtained and processed for ultrastructural study after whole body perfusion with 5% glutaraldehyde buffered with PO₄, osmication, dehydration and embedding in Epon⁴. Human CNS tissue was obtained at autopsy from a patient who had suffered from chronic relapsing MS for more than 20 yr, the autopsy being carried out some 30 min post-mortem. In the lumbar cord at L₃, a large demyelinated plaque was grossly visible in the anterior column. Thin transverse slices across this lesion were taken and immersed in glutaraldehyde for 60 min and then processed as above for electron microscopy.

Demyelinated plaques of different ages were common in spinal cord tissue of the guinea pig. They were usually subpial and displayed varying degrees of developing disease according to the frequency of relapses and recurrent inflammatory activity. Lesions were occasionally grossly visible. Chronically demyelinated plaques consisted of longitudinally arranged naked axons invested by fibrous astroglial tissue (Fig. 1a). Axons were readily distinguishable from astroglial cell processes on the basis of cross-bridged neurofilaments, abundant microtubules and a circular profile^{1,5}. Astroglial processes were flattened, contained a preponderance of tightly packed filaments (not cross-bridged), fewer microtubules, and had a tendency to invest axons in an

Fig. 1 a, Low power electron micrograph showing a group of transversely sectioned chronically demyelinated axons from a subpial lesion in the lateral column of a spinal cord at L₇. Note how the axons are intimately embedded in a matrix of fibrous astroglial processes. Chronic EAE, 16 weeks PI, one relapse. $\times 12,000$. b, Higher magnification of a demyelinated axon from a dorsal column lesion at L₇ shows regional enhancement of the axolemma due to thickening of the membrane and an associated subaxolemmal coating of granular material. In two places (arrows) corresponding thickening of the parallel arranged membrane of an investing astroglial cell process is shown, between which a cleft containing electron-dense material is present. Chronic EAE, 20 weeks PI, two relapses. $\times 35,000$. c, An astroglial process (g) separates three naked axons, between one of which (A) a synapse-like junction is seen. Note the vesicles in the axoplasm of the affected axon (A). Same preparation as Fig. 2. $\times 100,000$. d, The axolemma of a demyelinated axon (A) above appears to form a fenestra (arrow) with the membrane of an astroglial cell process (g). Same preparation as Fig. 2. $\times 200,000$.

Fig. 2 *a*, Low power view of a chronic MS plaque in an anterior column of the spinal cord at L₃. Note the intense glial scarring and the two demyelinated axons in transverse section. Chronic MS, over 20 yr duration, multiple relapses. $\times 12,000$. *b*, Detail from the above chronic MS plaque showing two axons (A) above and below, one of which displays a small desmosome-like junction which contacts others traversing several interposing fibrous astroglial cell processes. A gap junction is also seen (double arrows). $\times 60,000$.

haphazard fashion. Closer examination of the naked axons revealed regional densifications of the axon membrane on the axoplasmic side of which a narrow zone of osmiophilic granular enhancement was associated (Fig. 1*b*). Not infrequently, these specialised regions of axolemma apposed a similar region of densification on the investing astroglial membrane, and between the two, a 20–40 nm cleft within which a floccular substance could be discerned. These axon–astroglial membrane specialisations were very common (occurring in more than 60% of affected axons) and were present in all chronically demyelinated EAE lesions. They were not seen in normally myelinated regions, remyelinated zones, or in areas of recent demyelination. On two occasions, axons were seen to possess primitive ‘synapse-like’ junctions with investing astrocytic processes (Fig. 1*c*). These consisted of small desmosome-like structures in association with which were 60–80 nm diameter vesicles in the juxtaposing axoplasm. In addition, three axons were seen to possess fenestrae between adjacent astroglial cell processes. These occurred along zones of specialised axolemma where the membranes of the axon and the astrocyte fused to form a single unit membrane (Fig. 1*d*). Whether or not these fenestrae represented artefacts of sectioning remains to be elucidated by goniometer stage techniques (tilting). Elsewhere throughout the EAE plaques, a variety of junctional complexes was encountered between astroglial cell processes, particularly desmosomes, and gap and punctate junctions.

In the examined MS plaque, demyelinated axons were tightly packed in an intense fibrous astroglial matrix (Fig. 2*a*). Membrane imperfections due to the poorer fixation conditions were apparent. In contrast to the EAE material, extensive regions of membrane specialisation between axolemmae and adjacent astrocytes were not seen. Instead, more than 30% of the axons examined were seen to contact astroglia by means of small desmosomal junctions—regions of membrane some 150–200 nm in extent beneath which were broad zones of electron dense granular material. Sometimes, these complexes occurred in short series from an axon across several investing glial cell processes (Fig. 2*b*). In addition, many naked axons showed extensive subaxolemmal thickening, typical of that seen at nodes¹. Synapse-like arrangements were not encountered between axons and astroglia. Gap junctions (Fig. 2*b*) and small desmosomes were common between astroglial cell processes.

The present observations of membrane specialisations and possible junctional complexes between demyelinated axons and scarring glial cell processes in the adult CNS are unprecedented in neuropathology. However, somewhat similar membrane specialisations have been described previously in the spinal cord of the mouse during development, and have been termed puncta adherentia (*sic*) and axoglial synapses⁶. These connections represented a transient phenomenon and were not present after embryonic day 15. Their appearance was speculated “to reflect errors in development”, although their disappearance might have been linked to the development of more specific mechanisms. These unusual thickenings might represent transient phenomena or biological errors since they do not occur along normal or remyelinated fibres. The MS plaque under study was probably many years old (compared with the 2–6 months of the EAE plaques), and the areas of membrane specialisation may have undergone some further modification with time.

That these abnormal membrane relationships between axons and glia are the result of prolonged absence of myelin seems incontrovertible and they probably play some supportive role for the axon. However, whether they impart a compensatory property on the already impaired nerve fibre conduction remains to be established. In view of the frequent lack of correlation between clinical status and the extent of damage in the demyelinated CNS, the possibility that scarring astrocytes somehow unify naked fibres and are capable of participation in neural transmission, should be considered. Although the final characterisation of these junctional complexes must await freeze-fracture analysis⁷, on the basis of the frequency of these morphological peculiarities, retrospective examination of other models of CNS demyelination⁸ will reveal whether or not these specialisations are features only of immune-mediated demyelination.

Supersensitivity to the cyclic GMP response to glutamate during cerebellar maturation

THE action of certain neurotransmitters on receptors is associated with changes in the levels of cyclic nucleotides. Catecholamines, for example, increase cyclic AMP levels in both the central and peripheral nervous systems¹. In the adult brain the cerebellum contains the highest levels of cyclic GMP (ref. 2), and these can be altered *in vivo* by manipulation of excitatory pathways^{3,4} and intraventricular injection of γ -aminobutyric acid or glutamate^{3,5}, and *in vitro* by certain amino acid transmitter candidates^{6,7} and depolarising agents⁸. We show here that during a relatively short period in postnatal development, the excitatory amino acid, glutamate, elicits very large increases in the levels of cyclic GMP in slices of rat cerebellum, apparently located in the cells differentiating at this time.

Cerebella were rapidly excised from rats (Porton strain) of various ages, chopped (0.4 × 0.4 mm) at room temperature using a McIlwain chopper, and incubated at 37 °C in Krebs solution. The tissue was inactivated by boiling and, after homogenisation and centrifugation, cyclic nucleotides were estimated in the supernatant using commercial kits (Radiochemical Centre).

On addition of glutamate, cyclic GMP levels increased to reach a peak after 2–5 min irrespective of age (the time course at 8 d is shown in Fig. 1a). The extent to which they increased, however, was markedly age dependent. At 8 d (birth = day 1), maximal changes occurred at a glutamate concentration of 3 mM (Fig. 1b), with levels ($\pm$ s.e.m.) increasing from 0.56 ± 0.07 to 129 ± 5 pmol per mg protein, representing a >200-fold stimulation. This is considerably larger than any yet reported for non-tumorous nervous tissue. Changes of this magnitude were confined to slices from 8–14-d-old rats (Fig. 2). Either side of

Fig. 1 a, Time course and b, concentration dependence of the increase in cyclic GMP elicited by glutamate in slices of cerebellum from 8-d-old rats. Slices were preincubated (at about 1 mg protein ml⁻¹) for about 1.5 h (to allow cyclic nucleotide levels to stabilise) in Krebs solution containing (mM): NaCl (118), KCl (4.7), CaCl₂ (2.5), NaHCO₃ (25), KH₂PO₄ (1.18), MgSO₄ (1.19) and glucose (11), continuously gassed with a mixture of 95% O₂/5% CO₂ (pH 7.4) in flasks in a shaking water bath at 37 °C. At various times (a) or 5 min (b) after addition of glutamate, slices were removed using a Pasteur pipette, separated from the suspending medium by filtration and plunged into 1 ml of 50 mM Tris, 4 mM EDTA buffer, at 100 °C for 3–5 min. The interval between removal of slices and inactivation was <5 s. After homogenisation (through narrow gauge needles) and centrifugation, cyclic nucleotides in the supernatant fluid were measured. The protein content of the homogenate was estimated using the method of Lowry¹⁸. Points are the mean of 4–20 experiments, except for the 15-min point in a (mean of 2). Error bars are s.e.m. where this exceeds the dimensions of the symbol.

Fig. 2 Dependence on age. Solid circles show the cyclic GMP content in slices of cerebellum 5 min after the addition of glutamate (3 mM). Open circles are unstimulated levels, which show a developmental pattern similar to that found *in vivo* in mouse cerebellum², being fairly constant up to 8 d (at about 0.5 pmol per mg protein), increasing at 14 d (1.4 pmol per mg protein) and reaching adult values by 21 d (3–4 pmol per mg protein). At 1, 3 and 5 d, points show results of two experiments; at other ages, $n = 4-20$. The insert shows the corresponding levels of cyclic AMP (pmol per mg protein) with respect to age. Error bars are s.e.m. where this exceeds the dimensions of the symbols.

this period, the degree of stimulation fell markedly, such that in the newborn it was sixfold, at 21 d tenfold, and in the adult (70–90 d) only twofold. Cyclic AMP levels also increased in response to glutamate, but in contrast, these were similar for all ages studied, and small, only about twofold (Fig. 2).

An important consideration in interpreting these results is the relative degree of preservation of the cells and their processes in the incubated slices with respect to age. The observed developmental pattern of the cyclic GMP response up to 21 d is unlikely to reflect variation in tissue damage, as electron microscopy of slices incubated for 1.5–2 h showed good preservation of morphology up to 21 d, but in slices from older rats, swelling and pyknosis in neuronal and glial structures became evident, suggesting that the response observed with adult slices may be an underestimate.

The question arises as to the possible localisation of the response. In the rat cerebellum, 97% of the cells are formed postnatally⁹. At 8 d, cell proliferation, including that of the precursors of the granule cells, the most abundant cell type in the adult cerebellum, is extensive. The following experiments were carried out in an attempt to narrow down cell types possibly responsible for the increase in cyclic GMP.

The dividing cells were eliminated *in vivo* using the mitotic inhibitor hydroxyurea (HU); injection of HU at 6 d (2 mg per g body weight) results in an almost complete loss of the external germinal layer by 8 d^{10,11}, corresponding to a 35% decrease in cell numbers compared with controls (in terms of DNA content¹¹). In slices from 8-d-old, HU-treated rats, however, both basal and maximal glutamate-stimulated cyclic GMP levels were increased by 100% and 80%, respectively, compared with slices from untreated rats (Table 1a), indicating a localisation predominantly in those cells undergoing differentiation as opposed to proliferation.

The intracerebellar nuclei were not a major site of the response, as the increase of cyclic GMP levels in slices from the ventral two-thirds of the cerebellum (where the nuclei are found) was similar to that in slices from the dorsal one-third (in which the nuclei would be excluded) and from whole cerebellum (Table 1b).

In addition, if the response resided in the mature granule cells (excitatory interneurons), it would be anticipated (unless the early-maturing granule cells are unusual) that the measured

Table 1 Effect of removal of proliferating cells and intracerebellar nuclei on basal and glutamate-stimulated levels of cyclic GMP

	<i>n</i>	Cyclic GMP (pmol per mg protein)	
		Basal	+ Glutamate (3 mM)
<i>a</i> Treatment			
Saline	4	1.41 ± 0.13	167 ± 8
Hydroxyurea	4	2.87 ± 0.52	306 ± 13
<i>b</i> Part of cerebellum			
Whole	2	1.24, 0.84	131, 136
Dorsal, one-third	2	1.35, 1.32	141, 142
Ventral, two-thirds	2	0.92, 0.66	115, 132

In *a*, rats were injected on day 6 either with hydroxyurea (2 mg per g body weight, intraperitoneally) to delete proliferating cells, or with an equivalent volume of saline; cerebella were used 2 d later. In *b*, either whole cerebella (8 d) were chopped, and incubated as usual, or the dorsal one-third was separated by hand using a razor blade, and chopped and incubated separately from the ventral two-thirds. (The intracerebellar nuclei are found in the latter part.) Data in *a* are given as mean ± s.e.m.; in *b* individual results are shown.

degree of stimulation would parallel the large increase in their numbers over 7–15 d after birth¹², contrary to our findings.

Consequently, much of the glutamate-induced increase in cyclic GMP in the immature cerebellum is likely to originate in the cells formed prenatally and/or in cells formed before the eighth day (Purkinje cells, Golgi cells, inhibitory interneurons, glial cells).

The period of maximal elevation of cyclic GMP levels by glutamate (8–14 d) coincides with extensive morphological, electrical and biochemical maturation of the cerebellum¹³; by 21 d, the tissue is essentially mature. Assuming the response to be localised in the neurones, the magnitude of the observed changes in cyclic GMP and their confinement to this period in development might have implications regarding a role for transmitter-induced changes in cyclic GMP in maturing neurones in the cerebellum, for example, in the stabilisation of synapses¹⁴. We would add that this apparent 'supersensitivity' to glutamate does not extend to other putative neurotransmitters with action supposedly linked to cyclic nucleotide-generating systems. Changes in cyclic AMP levels induced by noradrenaline at 8 d (maximally a two- to threefold increase, J.G. and R.B., in preparation) were similar to those reported for the adult^{15,16} and, in contrast to the action of acetylcholine in slices of adult rabbit cerebellum¹⁷, the cholinergic agonist, carbachol, at concentrations of up to 1 mM, produced no significant change in cyclic GMP levels in slices of rat cerebellum at 8 d (J.G. and R.B., in preparation).

Calcium-dependent protein phosphorylation during secretion by exocytosis in the mast cell

IN many secretory cells materials destined for secretion are packaged in membrane-limited granules and are extruded by exocytosis¹. This process is known to require metabolic energy and calcium^{2–6}. Calcium probably acts as a common mediator in stimulus-secretion coupling², but the molecular mechanisms involved are unknown. Increasing evidence that many physiological processes are regulated by phosphorylation of proteins⁷ has led to the suggestion that calcium-dependent phosphorylation of proteins may be involved in secretory responses^{8–13}. We have sought evidence for this possibility in the mast cell, the rapid and extensive secretory activity of which conforms to the general pattern of exocytosis dependent on energy and calcium^{4,14–20}. Here we report a rapid phos-

Fig. 1 Effect of 48/80 and A23187 on endogenous phosphorylation of mast cell proteins. Peritoneal mast cells derived from 15 Sprague-Dawley male rats (~400 g) were collected and purified as described previously²⁸. Mast cells (80–90% purity, 1.5×10^6 cells ml⁻¹) were preincubated in a standard buffer (HEPES 5 mM, pH 7.0, NaCl 150 mM, KCl 5 mM and glucose 5.5 mM) in the presence of CaCl₂ 1 mM, 0.1% bovine serum albumin and 0.75 mCi ml⁻¹ carrier-free ³²P-phosphate (NEN, 9120 Ci mmol⁻¹) for 1 h at 37°C. The cells were centrifuged at 180g for 5 min at 4°C and resuspended in 5 ml standard buffer in the presence of 0.1 mM EGTA. The cells were centrifuged twice more, each time followed by a resuspension in the standard buffer. Mast cell suspensions (0.2 ml) were introduced into plastic tubes containing 48/80 1 µg ml⁻¹, A23187 1 µg ml⁻¹, calcium 1 mM or magnesium 1 mM, in 0.1 ml standard buffer. Following 1 min incubation at 37°C, 150 µl of a stop solution (10% sodium dodecyl sulphate (SDS; w/v), Tris-HCl 100 mM, pH 7.4, β-mercaptoethanol 5 mM, sucrose 0.1 g ml⁻¹ and bromophenol blue tracking dye 0.02 mg ml⁻¹) was added and the tubes were placed in a boiling water bath for 2 min. Electrophoresis on 10% polyacrylamide gels, protein staining of the gels, and autoradiography were carried out as described previously¹³. All radioactive bands disappeared after treatment of the samples with pronase but not with ribonuclease, using conditions described previously¹³, and thus represent phosphoproteins. The apparent molecular weights of the phosphorylated protein bands indicated by the arrows (78,000, P₇₈; 68,000, P₆₈; 59,000, P₅₉; 42,000, P₄₂) were determined by calibrating the gel with standard proteins of known molecular weight. Degranulation, used as a measure of mast cell secretion, was monitored by light microscopy²².

phorylation of several proteins in rat peritoneal mast cells stimulated to secrete either by the classic mast cell secretagogue 48/80 (refs 15 and 21–23) or by the calcium ionophore A23187 (refs 22–25).

Purified rat peritoneal mast cells, which had been preincubated for 1 h with $^{32}\text{P}_i$, were incubated for 1 min with 48/80 or A23187 in the presence or absence of calcium or magnesium. The cells were then dissolved in sodium dodecyl sulphate and subjected to polyacrylamide gel electrophoresis (PAGE) and autoradiography. Addition of compound 48/80 $1\text{ }\mu\text{g ml}^{-1}$, which caused extensive degranulation of the mast cells within 1 min, resulted in an increased phosphorylation of four proteins (of apparent molecular weights 78,000, 68,000, 59,000 and 42,000) (Fig. 1, compare lanes 1 and 2). This change in phosphorylation elicited by 48/80 did not require the presence of extracellular calcium (Fig. 1, lane 3). In these experiments, mast cell secretion elicited by 48/80 also occurred in the absence of calcium, in agreement with evidence that this secretagogue acts largely through mobilisation of intracellular calcium^{22,23,25,26}. The general pattern of phosphorylation seen in response to 48/80 was highly reproducible (14 experiments), although the increase in radioactive phosphate incorporated into these four proteins varied from one experiment to another. The phosphorylation of several other proteins was sometimes influenced by 48/80 (and A23187), but this effect was not consistent.

Fig. 2 Phosphorylation of mast cell proteins as a function of incubation time with 48/80 (a) or A23187 (b). Mast cells (0.2 ml), isolated and purified as described in Fig. 1, were introduced into plastic tubes containing either 48/80 $1\text{ }\mu\text{g ml}^{-1}$ or A23187 $1\text{ }\mu\text{g ml}^{-1}$, in 0.1 ml standard buffer containing calcium 1 mM. At the times indicated, 150 μl of stop solution was added and the phosphorylation of mast cell proteins was analysed by SDS-PAGE and autoradiography¹³. The amount of ^{32}P -phosphate incorporated into four proteins, P_{78} (○), P_{68} (△), P_{59} (●) and P_{42} (□), was determined by scanning the autoradiographs with a Canaco G-II microdensitometer. The results are expressed in arbitrary units²⁹. Results qualitatively similar to those shown here were obtained in four other experiments.

Phosphorylation of the proteins with apparent molecular weights of 68,000, 59,000 and 42,000 was evident within 10 s after addition of 48/80, whereas phosphorylation of the 78,000 protein was not evident until 30–60 s after addition of the secretagogue (Fig. 2). After being maximally phosphorylated, these four proteins displayed different rates of dephosphorylation. The fact that compound 48/80 binds almost exclusively to receptors on mast cell membranes²⁷ indicates that the proteins phosphorylated in response to this secretagogue are derived from mast cells rather than from other contaminating peritoneal cells (10–20%).

As in the experiments with 48/80, mast cells incubated with A23187 $1\text{ }\mu\text{g ml}^{-1}$ in the presence of calcium 1 mM showed increased phosphorylation of the proteins with apparent molecular weights of 68,000, 59,000 and 42,000 (Fig. 1, compare lanes 1 and 4). When calcium was omitted from the incubation medium, A23187 had a diminished effect on the phosphorylation of these proteins (Fig. 1, lane 5). In the absence of calcium, mast cell secretion was also diminished, in agreement with studies demonstrating only a feeble stimulant effect of A23187 on secretion under similar conditions^{24,25}. The residual effect on mast cell secretion and on protein phosphorylation seen with A23187 in calcium-free medium was abolished by magnesium (Fig. 1, lane 6). Magnesium has been shown to reduce residual mast cell secretion in a low calcium medium²⁴. The phosphorylation of the 78,000 band was decreased by A23187 both in the presence and in the absence of calcium but not in the presence of magnesium (Fig. 1). The time course of phosphorylation and dephosphorylation of the 68,000, 59,000 and 42,000 proteins (but not that of the 78,000 protein) in response to A23187 and calcium was generally similar to that observed in the presence of 48/80 (Fig. 2).

These results demonstrate that both 48/80, which is thought to mobilise calcium from intracellular stores, and A23187, which promotes entry of calcium into the cell, stimulate the phosphorylation of the same proteins at a time when the secretory response is still developing. Calcium-dependent protein phosphorylation may therefore be involved in stimulus-secretion coupling. As yet, however, the evidence that the two phenomena are causally linked is only suggestive.

Bromocriptine-induced inhibition of plasma dopamine, noradrenaline and adrenaline responses to LH-RF

In addition to their regulatory role on pituitary hormones, hypothalamic-hypophyseal regulatory hormones may function in brain as neurotransmitters. Thus, in addition to the considerable evidence in laboratory animals suggesting that the release of luteinising hormone releasing factor (LH-RF) is regulated by brain amines¹, further evidence suggests that LH-RF may function at central nervous system synapses. It is found within synaptosomes and vesicle-like structures in various areas of brain²; it influences animal behaviour through a direct action in brain³, and microiontophoretic applications of LH-RF to neurones in the mediobasal hypothalamus and preoptic area are associated with prominent short-term changes in neuronal excitability, the most frequently observed effect being decreased excitability⁴. It has been suggested that axon collaterals within a putative peptidergic neuronal network may function in feedback circuits regulating activity of the tuberoinfundibular system and to inform other brain regions about the activity of this system. It seems reasonable to speculate that LH-RF release from such peptidergic neurones may act as a neurotransmitter or modulator to regulate the activity of certain central aminergic neurones. Thus, we examined the effects of LH-RF on plasma catecholamines in normal men, and found a rapid decrease in plasma concentrations of dopamine, noradrenaline and adrenaline (Fig. 1). Furthermore, bromocriptine, a dopamine receptor agonist, entirely prevented this depressant effect of LH-RF on plasma catecholamines.

In men kept supine for 2 h in the absence of bromocriptine, basal plasma concentrations of dopamine, noradrenaline and adrenaline were 58 ± 1 (mean $\pm$ s.e.), 273 ± 3 and 92 ± 4 pg ml⁻¹, respectively. These are similar to values we have reported elsewhere^{6,7}. LH-RF produced rapid decreases in plasma concentrations of all three catecholamines (Fig. 1). Plasma concentrations of dopamine, noradrenaline and adrenaline 5 min after LH-RF administration were 65 ± 3 , 77 ± 3 and 48 ± 2 % of the pre-LH-RF basal levels, and 20 min after LH-RF, decreased further to 34 ± 3 , 35 ± 1 and 24 ± 0.5 % of basal levels.

We have reported elsewhere that bromocriptine decreases plasma concentrations of dopamine, noradrenaline and adrenaline⁷. However, 4 h after bromocriptine administration, plasma concentrations of all three catecholamines had returned to basal levels. LH-RF administered at this time failed to suppress plasma concentrations of dopamine, noradrenaline and adrenaline (Fig. 1). Thus, bromocriptine interfered with the effect of LH-RF on plasma catecholamines at a time when its own effect on catecholamine release had apparently ended, although its effect on serum prolactin was still present.

Bromocriptine seems to produce many of its effects through an action on dopamine receptors⁸. Although evidence has been presented for an action on postsynaptic dopamine receptors⁹, more recent evidence supports an effect on presynaptic receptors¹⁰. We have suggested that bromocriptine may decrease plasma catecholamine concentrations by an action on presynaptic receptors of unknown central catecholaminergic neurones mediating sympathetic outflow, although a similar action on peripheral neurones could not be ruled out⁷.

It seems reasonable to speculate that LH-RF may act in a manner similar to that of bromocriptine. Alternatively, LH-RF

Fig. 1 Plasma dopamine, noradrenaline and adrenaline responses to LH-RF in the absence (●) and presence (○) of bromocriptine. Studies were carried out in three normal men, aged 36, 38 and 50 yr. An indwelling intravenous cannula was inserted into an antecubital vein of each subject on two occasions, with the subjects supine after fasting for 14 h. Blood (12 ml) was sampled for plasma catecholamines and serum prolactin, LH and FSH on each occasion, 1 and 5 h after cannula insertion and before administration of LH-RF. Subjects remained supine during this period except for a 5-min period of standing, 2 h after cannula insertion. LH-RF, 100 µg, was administered intravenously as a bolus and blood was sampled further, 5, 20, 60 and 120 min later. On the first occasion, bromocriptine had been taken orally 2.5 mg daily for 3 d, then 2.5 mg q12 h for another 4 d. A final dose of bromocriptine was administered 1 h after cannula insertion, that is, 4 h before LH-RF. On the second occasion, no bromocriptine had been taken for 2 weeks and none was administered during that part of the study. This allowed comparison of the plasma catecholamine response to LH-RF in the presence and absence of bromocriptine. Blood (2 ml) for catecholamine assay was transferred to tubes containing 4 mg of dithiothreitol and 20 µl of EGTA solution, 100 mg ml⁻¹. Plasma was separated and stored at -70°C until assay for catecholamines⁵. a, Dopamine; b, noradrenaline; c, adrenaline. * $P < 0.01$, significantly different from basal level. ** $P < 0.001$.

might act on presynaptic receptors of peripheral catecholaminergic neurones to decrease plasma catecholamines. It might act on dopamine receptors¹¹ or α -adrenoreceptors¹² to inhibit noradrenaline release from noradrenergic neurones as we discussed for bromocriptine⁷. It might also decrease dopamine release from peripheral dopaminergic or noradrenergic neurones. LH-RF-induced depression of adrenaline release, most of which probably comes from the adrenal medulla, is more difficult to explain by a peripheral rather than a central mechanism. If the LH-RF effect on plasma adrenaline is centrally mediated, it seems more probable that the effects on plasma dopamine and noradrenaline are also mediated centrally rather than peripherally.

Further support for the suggestion that LH-RF may decrease plasma catecholamines by acting directly on presynaptic receptors of catecholaminergic neurones is provided by our observations that bromocriptine prevents the LH-RF-induced depression of plasma catecholamines. Bromocriptine interfered with this effect of LH-RF at a time when its own effect on plasma catecholamines had ended. However, as the effect of bromocriptine on serum prolactin levels persisted at this time, it is possible that it still occupied dopamine receptors.

Further evidence that LH-RF may act on central catecholaminergic neurones is provided by our observations in rats that LH-RF decreased hypothalamic dopamine- β -hydroxylase activity (G.R.V.L. and R. Mascardo, unpublished).

In addition to its well known effects on serum LH and FSH, LH-RF increased serum prolactin in our normal men (Table 1). Such an effect might be mediated directly on anterior pituitary

Table 1 Serum prolactin, LH and FSH responses to LH-RF in the absence and presence of bromocriptine

Time (min)	Prolactin (ng ml ⁻¹)*		LH (mU ml ⁻¹)*		FSH (mU ml ⁻¹)*	
	Control	Bromocriptine†	Control	Bromocriptine†	Control	Bromocriptine†

* Serum prolactin, LH and FSH were assayed by standard radioimmunoassay methods described elsewhere. All values are concentration means ± s.e.m.

† Bromocriptine 2.5 mg administered orally 240 min before LH-RF.

‡ All Pre-LH-RF values are pooled means of 18 determinations, six samples taken at intervals during the 4 h before LH-RF administration from each of the three subjects.

§ LH-RF, 100 µg, was administered as an intravenous bolus.

|| Significantly different from Pre-LH-RF concentration at $P < 0.05$ using analysis of variance and Duncan's multiple range test.

cells or indirectly in the median eminence. If LH-RF inhibits dopamine release from tuberoinfundibular dopaminergic neurones, as speculated above for catecholamine neurones generally, and dopamine acts to inhibit prolactin secretion, then increased prolactin secretion could be expected following LH-RF administration. Bromocriptine prevented this LH-RF-induced increase in serum prolactin, providing another parallel with the interference of LH-RF-induced effects on plasma catecholamines. There were no apparent effects of bromocriptine on the plasma LH and FSH responses to LH-RF.

If the effects of LH-RF on plasma catecholamine concentrations are mediated through presynaptic receptors as suggested above then the presynaptic receptor mechanisms involved must be functionally intact to produce a normal response. Thus, the plasma catecholamine response to LH-RF may provide an index of normal function of certain catecholaminergic neurones in man. As a corollary, dysfunction of certain catecholamine neurones might be demonstrated by abnormal plasma catecholamine responses to LH-RF. Support for this hypothesis is provided by the demonstration that in contrast to normal men, patients with acromegaly show no changes in plasma dopamine, noradrenaline or adrenaline following LH-RF administration¹³. Thus, acromegaly may represent a disorder of catecholaminergic neurones. Furthermore, the plasma catecholamine response to LH-RF may prove useful as a test of catecholaminergic dysfunction in a wide variety of disorders such as Parkinson's disease, essential hypertension, autonomic neuropathies and poorly defined hypothalamic disorders.

I thank Drs J. Bain and J. Ruse for taking part in the study and J. Sturdy for technical assistance. The study was supported in part by grant MA-5183 from the MRC of Canada. I thank Saneloz for bromocriptine (Parlodel) used in the study.

New structural concepts for narcotic antagonists defined in a 4-phenylpiperidine series

NARCOTIC antagonists are generally considered as *N*-methylcyclopropyl or *N*-allyl (for example, nalorphine) type derivatives of *N*-methyl (for example, morphine) agonists. This type of substitution has often been considered necessary for potent narcotic antagonist activity^{1,2}. However, in the 4-phenylpiperidine series (as in meperidine) where a methyl substitution on the nitrogen has been associated with agonist activity, the substitution of an *N*-allyl derivative has not produced narcotic antagonists³⁻⁵. There are compounds, such as *L*-metazocine^{6,7} and profadol⁸, which contain a methyl-substituted basic nitrogen, and possess narcotic antagonist properties, but these are also agonists and their antagonist activity is relatively weak. During the pharmacological investigation of a new series of phenylpiperidines we discovered an *N*-methyl derivative that was a pure narcotic antagonist devoid of agonist effects. We also observed that nitrogen substituents that had increased agonist potency in the meperidine series⁹ when substituted in compounds of the present series surprisingly augmented antagonist potency to the level observed with naloxone⁴. Examination of the inhibition of specific ³H-naloxone binding of these derivatives in bovine striatal membranes demonstrated that their relative potency was due to differences in receptor interaction. We used the most potent member of the series to study its stereoselectivity. We report here the structure-activity relationships of some 1,3,4-trialkyl-4-phenylpiperidines that clearly demonstrate the importance of a 3-methyl substituent in contributing narcotic antagonist properties within the phenylpiperidine series as a whole. These compounds may well represent the first new class of pure narcotic antagonists since the discovery of naloxone.

Narcotic antagonist measurements for the 1,3,4-trialkyl-4-phenylpiperidine series are shown in Table 1. The AD₅₀ (dose that reduced the morphine response by 50%) for the *N*-methyl compound (I) was 0.24 mg per kg in rats and 1.0 mg per kg in mice. These values are comparable to the AD₅₀ values for

nalorphine of 0.4 mg per kg and 0.45 mg per kg in rats and mice, respectively. The allyl (II) and methylcyclopropyl (III) substitution did not increase the antagonist potency, as might have been expected in a multicyclic series (for example, morphinan⁴ and benzomorphan¹⁰). There was an increase in antagonist potency when the *N*-methyl was changed to *N*- β -phenethyl (IV) or *N*-2-propiofenone (V). Antagonist potency of the *N*-propiofenone derivative (V) was comparable to that of naloxone. Resolution of the 2-propiofenone (V) into its (+)-isomer (VII) and (-)-isomer (VI) provided only partial separation of activity, as both were antagonists, with the (+)-isomer being 2–6 times more potent than the (-)-isomer.

The 1,3,4-trialkyl-4-phenylpiperidines (Table 1) were pure antagonists as judged by the following observations. They were without measurable narcotic agonist activity (analgesia) at 100 mg per kg, given subcutaneously (s.c.), in the mouse writhing analgesic test, where compounds with mixed agonist/antagonist activity (such as nalorphine) exhibit analgesic effects (method previously described¹¹). More convincingly, in an *in vitro* measurement sensitive to narcotic agonist effects and free of the influence of metabolism, the *N*-propiofenone (V) was without measurable narcotic agonist effects. This lack of effect *in vitro* was on the twitch height of the electrically stimulated longitudinal muscle of the guinea pig ileum (method previously described¹¹). Compounds with mixed agonist/antagonist properties depress the twitch height in relation to the potency of their agonist effects, whereas pure antagonists (such as naloxone) show negligible depressant effects¹⁰. Compound V, like naloxone, lacked agonist activity at 10 μ g ml⁻¹, but completely antagonised the narcotic agonist effects of morphine at a concentration of 10 ng ml⁻¹.

The increase in antagonist potency observed when the *N*-methyl is changed to *N*-propiofenone is particularly interesting because this substitution is known to enhance agonist activity in the meperidine and prodine series⁹. Table 2 shows the receptor affinities of these 1-alkyl- β -3,4-dimethyl-4-phenylpiperidines as measured by their inhibition of ³H-naloxone binding to bovine striatal membrane homogenates in the presence and absence of NaCl. The rank order of the IC₅₀ values for compounds I–V closely parallels the observed *in vivo* antagonist potencies given in Table 1. The *N*-methyl (I), *N*-allyl (II) and *N*-methylcyclopropyl (III) derivatives all had relatively high IC₅₀ values. However, substitution of the *N*-methyl group by either the *N*- β -phenethyl (IV) or *N*-2-propiofenone (V) groups resulted in a 100-fold increase in competitive binding, comparable to that of nonradioactive naloxone. The ³H-naloxone binding of these derivatives was essentially unchanged in the presence of NaCl, confirming their binding to be that of a narcotic antagonist¹².

The importance of the methyl at position 3 on the piperidine ring is shown in Table 1. Compound IX, a reported narcotic agonist¹³ lacking the 3-methyl moiety, is devoid of narcotic antagonist activity. Table 1 also shows the structural specificity of the antagonist activity in that the 3- α -methyl isomer (VIII) (*cis*-3-methyl, 4-methyl) is about 50 times less active than the 3- β -methyl isomer (I) (*trans*-3-methyl, 4-methyl). The significance of the 3-methyl substitution is further indicated in Table 1. A methyl substituted on the position of the ketobemidone molecule provided a weak antagonist (X), which contrasts sharply with the potent agonist effects of ketobemidone¹⁴. The 3-methyl ketobemidone derivative (X) is a mixed agonist/antagonist producing inhibition of writhing (analgesia)

Table 1 1,3,4-trialkyl-4-phenylpiperidines and their narcotic antagonist activities

Compounds I–VIII were prepared in a multiple-step procedure starting from 3-methoxyphenylacetone. The isomeric configurations were confirmed by X-ray crystallography and ¹³C-NMR analysis. Compounds IX (ref. 13), X (ref. 16) and XI (ref. 17) were synthesised by modified published procedures. Water-soluble salts were prepared in all instances. The ability of each test compound to reduce the opiate effect of morphine was measured in mice by determining the antagonism of the morphine-induced Straub tail and increased locomotion. Fasted male Cox Standard albino mice (17–21 g) were used. Morphine sulphate was administered at 40 mg per kg, s.c., and the presence or absence of the Straub tail and increased locomotion were noted and scored 15 min later. The test antagonist was administered s.c. at various doses 15 min before the morphine sulphate. The ability of the test compound to reduce or antagonise the analgesic effect of morphine was measured in the rat tail heat analgesic test (previously described¹⁰). The only change in the method was to increase the stimulus by using 7 A currents in the heating wire. We routinely measured the analgesic effect of morphine sulphate 10 min after the s.c. administration of 10 mg per kg. The elevations in reaction time following morphine were 2.5–8.6 s, with the average of 24 groups being 4.8 s. The test antagonist was administered s.c. at various doses 20 min before the morphine sulphate. The increase above controls for the morphine group was compared to the group receiving both morphine and the antagonist, and the % reduction in the morphine response determined. The AD₅₀ value, determined by "the use of the regression line in reverse"¹⁸ was the dose required for a 50% reduction in the response to morphine.

* *trans*-3-methyl, 4-R.

† *cis*-3-methyl, 4-R.

‡ Compound IX lacks the 3-methyl group.

Table 2 Inhibition of ³H-naloxone binding by 1-alkyl-β-3,4-dimethyl-4-phenylpiperidines in the presence and absence of NaCl

Compound	Concentration of compound at 50% inhibition (IC ₅₀ , nM)		Na shift (+NaCl/−NaCl)
	+NaCl	−NaCl	
I	50	100	0.5
II	60	90	0.7
III	60	60	1
IV	0.4	1.5	0.3
V	2	1	2
Naloxone	1.2	1.6	0.8
Levorphanol	60	2	30

Bovine striatal membranes of 0.6 mg protein were incubated at 24 °C for 15 min in 1 ml of 100 mM Tris-Cl, pH 7.4 buffer containing 2 nM ³H-naloxone (38 Ci mol^{−1}, NEN) and 100 mM NaCl as indicated. Samples were centrifuged at 1,085g for 10 min. Radioactivity in the pellet was determined by a liquid scintillation method. The IC₅₀ value was obtained by plotting % inhibition against a 4-decade change in concentration of each compound in a semilog plot. Specific binding of ³H-naloxone was defined as the difference in binding between samples with and without 1 μM naltrexone. In control samples, ³H-naloxone was specifically bound to bovine striatal membranes at 40.8±1.5 and 119.7±2.6 fmol per mg protein in the absence and presence of 100 mM NaCl, respectively. Other experimental conditions were followed according to published methods¹⁹.

in mice at 10 mg per kg, s.c. Hydroxylation of the phenyl in β-prodine, a compound already possessing the appropriate 3-methyl, changed this potent agonist¹⁵ into a narcotic antagonist (XI) with a greater potency than that of pentazocine, but lacking measurable agonist activity.

In summary, we report here the discovery of several novel phenylpiperidines which are potent narcotic antagonists without measurable agonist properties. We believe that this defines a new class of narcotic antagonists in which the 3 position of the piperidine ring rather than substitution at the nitrogen is the area critical for determining antagonist activity.

We thank Bud Cantrell for compound synthesis, Bill Kurtz, John Henderson and Henry Miles for technical assistance, Endo for naloxone hydrochloride, and Sterling Winthrop for pentazocine.

Viral sequences related to a human skin papillomavirus in genital warts

GENITAL WARTS (condylomata acuminata) are benign tumours which are mostly venereally transmitted¹; their malignant conversion has been observed only rarely (see refs 2, 3 for reviews). Typical viral particles, long believed to be those of the human papillomavirus (HPV) found in skin warts⁴, were observed irregularly in these lesions^{5–7}. Epidemiological¹ and serological⁶ data, as well as molecular hybridisation experiments showing the absence of DNA sequences homologous to skin HPV DNA in condylomas^{8,9}, have raised the possibility that these lesions are due to a distinct HPV. However, the demonstration of at least four distinct HPV types in skin lesions^{10–13} requires a reexamination of this problem. We have identified four types of HPV showing little, if any, DNA sequence homology and distinct serological properties: HPV type 1 (HPV-1) associated with deep plantar warts¹², HPV type 2 (HPV-2) isolated from common warts¹², HPV type 3 (HPV-3) found in flat warts and in flat wart-like lesions of patients suffering from epidermodysplasia verruciformis (EV)¹³ and HPV type 4 (HPV-4) isolated from morphologically distinct EV lesions (reddish or pityriasis versicolor-like plaques)¹³. HPV-4 is found more frequently than HPV-3 in patients with EV showing a malignant conversion of some lesions^{13,22}. We report here RNA–DNA hybridisation data indicating that genital warts are associated with an HPV showing little, if any, DNA sequence homology with HPV-1, HPV-2 and HPV-3 and a low extent of homology with an HPV-4 isolate taken as prototype in previous studies¹³.

Fig. 1 Agarose gel electrophoresis of DNAs extracted from genital warts. Warts obtained from seven patients (Table 1) were processed according to a modified Hirt method^{12,14}. Minced tissues (0.3–1 g) were incubated in 10 ml of 0.01 M Tris, 0.01 M NaCl, 0.01 M EDTA, 0.5% SDS containing 50 μg ml^{−1} of proteinase K (Merck). After a 6 to 10 h incubation at 37 °C, NaCl concentration was adjusted to 1 M, and the mixtures were kept at 4 °C overnight. Supernatants were extracted twice with phenol and DNAs were ethanol-precipitated and redissolved in 0.5–1 ml of 0.01 M Tris, 0.001 M EDTA, pH 7.9. Yields of DNA ranged from 0.04 to 1 mg as determined by absorbance at 260 nm. DNAs (30–300 μg per slot) were fractionated by electrophoresis in vertical 0.8% agarose slab gels (0.04 M Tris, 0.02 M ammonium acetate, 0.002 M EDTA, pH 7.8) for 20 h at 30 mA, taking HPV-1 form I, II and III DNA as standards (10 μg DNA per slot). Gels were stained in 5 μg ml^{−1} ethidium bromide and electropherograms visualised under UV light, as shown for the DNAs extracted from genital warts of patients N.M. (a), W.K. (b) and M.B. (c) and for HPV-1 form I, II and III DNA (c, d). The slower migration of the genital wart HPV DNA is probably due to the high viscosity of the samples.

Fig. 2 Electron micrographs of circular HPV DNA molecules obtained from genital warts. DNAs were selectively extracted from lesions of patients W.K. (a), W.L. (b) and M.B. (c) and further purified by Agarose gel electrophoresis as described in the legend to Fig. 1. Bands with a mobility comparable to that of HPV-1 form I DNA molecules were sliced from the gel and DNA was eluted electrophoretically, mounted on collodion-coated grids, Pt-Pd shadowed and observed with a Siemens Elmiskop 101 electron microscope¹². The arrow indicates a molecule of replicative form of Φ X174 phage DNA (Φ X174 RF DNA), taken as length standard. The bar represents 0.5 μ m.

The present study was carried out with genital warts obtained from seven patients (Table 1). Because the low virus content of lesions^{5,7,9} precluded virus purification, viral DNA was extracted selectively from the tissues^{12,14} and purified by Agarose gel electrophoresis¹⁵ (Fig. 1). Four of the DNA preparations did not yield detectable bands (Fig. 1a). However, preparations obtained from patients W.K., W.L. and M.B. showed bands migrating slightly more slowly than those of HPV-1 form I, II or III DNA (Fig. 1b-e). Circular DNA molecules of about 2.5 μ m, typical of HPV DNAs¹⁶ (Fig. 2), were observed in electrophoretic eluates of the bands corresponding to form I DNA. This result is in contrast to the previously reported failure to demonstrate the presence of a distinct papova-like circular DNA in condylomata acuminata⁹. Comparable length distributions were found for W.K. and M.B. HPV DNAs purified by Agarose gel electrophoresis (Fig. 3a, c) and for W.L. HPV

DNA molecules found in total DNA (Hirt supernatant) (Fig. 3b). The lengths of W.K., M.B. and W.L. HPV DNAs were 1.493 ± 0.08 , 1.439 ± 0.07 and 1.462 ± 0.08 Φ X174 RF DNA units, corresponding to 8,025, 7,735 and 7,860 base pairs, respectively. Molecular weights inferred from these values ($5.2-5.3 \times 10^6$) are close to those determined for the DNAs of the HPVs so far identified^{12,13}. A second population of circular DNA molecules, about 5.1 μ m long, was observed in the total W.L. DNA preparation (Fig. 3b). This could represent either HPV DNA dimers or, more probably, mitochondrial DNA molecules^{9,18}.

Fig. 3 Histograms of the lengths of genital wart HPV DNA molecules. DNA selectively extracted from lesions (b, W.L.) and further purified by Agarose gel electrophoresis (a, W.K.; c, M.B.) (see legend to Fig. 2) were mixed with Φ X174 RF DNA molecules. Contour lengths of relaxed circular molecules were measured on electron micrographs and expressed as fractional length of Φ X174 RF DNA¹².

Total DNA from genital warts, as well as purified form I DNA preparations (W.K. and M.B. HPV DNAs), were hybridised with RNAs complementary (cRNAs) to HPV-1, HPV-2, HPV-3 or HPV-4 DNAs^{12,13}. In these conditions^{12,13,20}, 50-60% of the radioactivity bound to the filters after hybridisation of

RNA-DNA filter hybridisation under paraffin was carried out as described by Kourilsky *et al.*²⁰ with triated RNAs (specific activity, $3-4 \times 10^7$ c.p.m. μ g⁻¹) complementary (cRNAs) to the four HPV DNAs transcribed *in vitro* as previously described¹². HPV DNAs were obtained from a single plantar wart (HPV-1)¹², pooled hand common warts of a single patient (HPV-2)¹², and pooled scrapings of lesions of two patients with E.V. (HPV-3, HPV-4)¹³; these HPV-2, HPV-3 and HPV-4 preparations were those taken as prototypes in previous studies^{12,13}. Genital wart DNAs were selectively extracted from the lesions of seven patients according to a modified Hirt procedure^{12,14} (total DNA) or further purified by Agarose gel electrophoresis (eluate), as described in the legends to Figs 1 and 2. Nitrocellulose filters (two per assay) carrying heat-denatured prototypical HPV DNAs, W.K. and M.B. HPV DNAs (about 50 ng, as determined with Φ X174 RF DNA as a standard²¹), genital wart DNAs (2.5-7.5 μ g), human fetal thymus or liver DNA (7.5 μ g), as well as blank filters, were added with 4 μ l of cRNA (2,000 c.p.m. per filter) in 0.30 M NaCl, 0.030 M sodium citrate-50% formamide. Heat-denatured fetal human thymus DNA was added to the hybridisation mixture (0.5 μ g per assay) to eliminate any hybridisation to cellular DNA on filters. Paraffin was added and filters were incubated for 15 h at 37 °C, processed and counted as previously described¹². Sex and age (yr) of patients are given in parentheses.

homologous viral DNAs and cRNAs, whereas no radioactivity was retained using heterologous prototypical cRNAs and DNAs (Table 1). No significant hybridisation was obtained with any of the genital wart DNAs (total or form I) and HPV-1, HPV-2 or HPV-3 cRNAs. However, all the total DNA preparations, as well as purified form I DNA from W.K. and M.B. tumours, showed significant levels (3.5–8.8%) of hybridisation with the HPV-4 cRNA probe (Table 1).

Our results indicate that three known types of human papillomavirus, HPV-1, HPV-2 and HPV-3, are not generally associated with genital warts (see, however, ref. 22). On the other hand, we find that viral sequences related to a fourth type, HPV-4, are present in DNA of the tumours studied here. The present data do not, however, show to what extent the sequences are related, and this remains a subject for further study.

We thank P. Sheldrick and F. Breitburd for discussion and critical reading of the manuscript, and N. Jibard, D. Fortin, C. Danguet and D. Cany for assistance. An insert in the single gene for the large ribosomal RNA in yeast mitochondrial DNA

MITOCHONDRIAL DNA (mtDNA) contains genes for the ribosomal RNAs (rRNAs) and transfer RNAs (tRNAs) used in mitochondrial protein synthesis and for a limited number of proteins of the mitochondrial inner membrane^{1–4}. By a combination of genetic and physical mapping, the location of most of these genes on yeast mtDNA has been determined^{3,4}. There is a single gene for the RNA from the large subunit of

Fig. 1 The physical map of mtDNA from *S. cerevisiae* strain JS1-3D, showing the position of the rRNA genes and the recognition sites for endonucleases *HindII* and *HindIII* and the single site for endonuclease *SalI* (from refs 5, 10). The contour length is 72,000 base pairs. The region of the map enlarged in Fig. 2 and the segment of mtDNA retained in petite mutant F41 are indicated.

yeast mitochondrial ribosomes⁵, but, nevertheless, this RNA hybridises to non-adjacent fragments on the physical map of mtDNA⁶. Although this suggested that the gene for this RNA is split, like some eukaryotic nuclear genes⁷, the presence of partial gene duplications complicated the interpretation of our hybridisation experiments⁶. By electron microscopy of RNA-DNA hybrids we now present direct evidence for an insertion in this rRNA gene.

Figure 1 shows a simplified map of yeast mtDNA, and Fig. 2 gives a more detailed map of the region of the large rRNA cistron. The rRNA hybridises to the *HindII* and *HindIII* fragments TD9, DT14 and TT1 (hatched in Fig. 2), but not to TD15 and the small 70-base pair fragment next to it⁶. Additional hybridisation experiments (unpublished) have shown that this is not due merely to partial gene duplication, because no homology was found between sequences hybridising with 21S rRNA in fragment TT1 and fragment TD9.

To prove that the rRNA gene is indeed split, hybrids were made between rRNA and the *HaeIII* fragment indicated in Fig. 2. The rRNA was obtained by fractionating total mtRNA from *Saccharomyces cerevisiae* strain JS1-3D by agarose gel electrophoresis and eluting the 21S rRNA band 8. The *HaeIII* fragment was isolated⁹ from the mtDNA of petite mutant F41. This petite has been derived from *S. cerevisiae* strain JS1-3D; it contains the segment of wild-type mtDNA indicated in Fig. 1 which has been shown by restriction enzyme digestion and hybridisation analysis^{6,10} to be identical to the corresponding wild-type sequence. Hybrids were formed in high formamide concentration to avoid DNA renaturation¹¹, and spread in conditions which allow a clear distinction between single-stranded RNA (kinky) and DNA (smooth) strands. Figure 3 shows two of the predominant hybrid molecules present in electron micrographs of these hybrids and the insert gives our interpretation of these molecules. The single-stranded DNA loop between two duplex hybrid sections proves that the mature rRNA is complementary to non-adjacent segments of mtDNA. Not a single full-size hybrid molecule without this loop was observed. The left-right orientation of the hybrid molecules relative to the map in Fig. 2 is determined by the morphology of the single-stranded ends, which shows that the left-hand end is RNA and the right-hand end DNA. This orientation was confirmed by the presence of rare hybrid molecules that had reannealed with a broken complementary DNA strand of the *HaeIII* fragment, resulting in hybrids with a partially duplex end. This duplex end was present at the side of the short hybrid segment (segment c in Fig. 3).

Table 1 Size of hybrid and single-stranded DNA regions in 42 rRNA hybrid molecules

Segment (see Fig. 3)	$\mu\text{m} \pm \text{s.d.}$	Size Base pairs
a	0.33 ± 0.02	830
c	0.20 ± 0.01	510
b	0.50 ± 0.03	1,160

Measurements of hybrid sections were calibrated with the circular replicative form of phage ΦX174 (5,375 base pairs²⁰), co-spread and measured on the same grid. Single-stranded DNA segments were calibrated using the single-stranded *HaeIII* fragment (4,300 nucleotides) present on the same grid.

The position of the rRNA gene on the map in Fig. 2 follows from the quantitative information on 42 hybrid molecules summarised in Table 1 and from the sections of the DNA previously shown to hybridise with rRNA^{6,10}. The location of the insert is determined by the size of section a (830 base pairs) and the position of the left-hand end of the *HaeIII* fragment¹², which we have mapped by double-digestion analysis. The size of the insert, determined from the size of loop b, is 1,160 base pairs. From the size of sections a–c, we infer that the rRNA cistron runs about 400–500 base pairs into fragment TT1.

Although inserts have previously been found in the nuclear rRNA genes of *Drosophila*^{11,13–16}, it has not yet been possible to decide if these split genes yield mature rRNA. With yeast mtDNA this is certain, because no other gene is present.

The region of the 21S rRNA on yeast mtDNA contains interesting structural and genetic elements, as indicated in Fig. 2. First, there is the 1,050-base pair insertion VI of Sanders *et al.*⁵ found by us^{5,6} and by Jacq *et al.*¹² in the ω^+ strains and lacking in the ω^- strains characterised by Slonimski *et al.*¹⁷. This 1,050-base pair insertion coincides with the intervening sequence in the rRNA gene within the limits of error of our measurements. Other interesting genetic loci are *rib-1* (chloramphenicol resistance) and *rib-2* (erythromycin resistance). We have argued previously¹⁸ that mutations at these loci affect the mitochondrial ribosome by altering the nucleotide

Fig. 2 The physical map of the segment of yeast mtDNA that contains the gene for the large 21S rRNA. The position of the cleavage sites for endonucleases *HindII*, *HindIII*, *HapII* and *SalI* on the mtDNA of *S. cerevisiae* strain JS1-3D are taken from refs 5, 6 and 10. Hatched fragments hybridise with 21S rRNA^{6,10}. The position on the map of the *HaeIII* fragment, used for electron microscopy of DNA–RNA hybrids, was determined by double-digestion analysis with endonucleases *SalI*, *HindII* and *HindIII* (unpublished). The position of the rRNA gene was deduced from the hybridisation results^{6,10} and the measurements in Table 1; from the size of the rRNA (3,700 nucleotides²¹) we infer that the left border of the rRNA gene must be close to the left *HapII* site in TD9, as drawn, but this has not been verified. The positions of the genetic loci are taken from ref. 10 and unpublished results; ω is a locus which affects the recombination of markers around it; there is a one-to-one correlation^{6,12} between the ω^+ allele and insertion VI of Sanders *et al.*⁵. Mutations at *rib-1* and *rib-2* confer insertion of mitochondrial protein synthesis to chloramphenicol and erythromycin, respectively. *rib-1* and *rib-2* are most probably located in the region indicated by the continuous line, but a position more to the right, indicated by the broken line, is not excluded.

Fig. 3 Electron micrograph of RNA–DNA hybrids made between 21S rRNA and the denatured *HaeIII* fragment indicated in Fig. 2. The hybridisation and visualisation of hybrids was done by the procedure of Wellauer and Dawid¹¹ as described²², with the modification that the hybridisation was carried out for 2 h at 40 °C. Main figure electron micrograph showing two adjacent hybrid molecules; scale bar, 0.2 μm . Inset, interpretation of main figure; dotted lines are RNA, straight lines DNA.

sequence of rRNA. The precise mapping of these loci, on the one hand, and of the rRNA, on the other hand, now lends support to this suggestion.

In previous papers^{4,6,19} from our laboratory, it was suggested that the genes for subunit I of cytochrome *c*-oxidase (*oxi-3* locus) and for cytochrome *b* (*cob* locus) are split to account for the discrepancy between apparent locus size and protein product. Our present results re-emphasise this suggestion. Yeast mitochondria with their simple and well-characterised genome⁴ may well turn out to be an attractive experimental system for the study of the nature and evolution of gene inserts and the splicing enzymes required to process the primary transcripts of such genes.

Yeast has a true stringent response

IN bacteria there is a coordinate regulation of the synthesis of ribosomal RNA and ribosomal protein¹. This is most evident from studies of the rates of synthesis of ribosomal components as a function of the growth rate of the cell^{2,3}. Another example is the 'stringent response', in which cells deprived of an essential amino acid shut down the transcription of ribosomal RNA as well as that of messenger RNA for ribosomal proteins^{4,5}, but increase the synthesis of mRNA for certain biosynthetic proteins⁶. Although this stringent response is at least partially due

Fig. 1 Macromolecular synthesis in cells deprived of tyrosine. Protein synthesis (●): *Saccharomyces cerevisiae*, strain A364A, a, *ade*⁻, *ura*⁻, *his*⁻, *lys*⁻, *try*⁻, were cultured in synthetic complete medium at 23 °C as described elsewhere⁷, to a concentration of 1×10^7 . The cells were collected by filtration, washed and suspended in medium lacking tyrosine. At various times 5 ml of culture was added to a flask containing 2.5 μ Ci of ¹⁴C leucine (120 μ Ci μ mol⁻¹). At 5-min intervals for 30 min, 0.5 ml of culture was transferred to 1 ml 10% trichloroacetic acid (TCA), boiled briefly and the acid insoluble radioactivity determined. The rate of incorporation was determined from the slope of the resultant curves compared with the rate of incorporation of the culture before the medium change, and plotted at the midpoint of the 30-min incorporation. Ribosomal RNA transcription (▲): cells were deprived of tyrosine as described above. At intervals, a 3-ml aliquot was mixed with 0.5 mCi of ³H (methyl) methionine. After 60 s the culture was chilled and the RNA extracted from broken cells and analysed on 2.75% polyacrylamide gels as described⁷. The radioactivity in RNA species was normalised to the absorbance of 25S RNA and compared with the value for a culture labelled before the medium change. Template activity (○): cells were deprived of tyrosine as described above. At intervals, 25-ml aliquots were chilled and total RNA prepared. The template activity of each preparation was determined at limiting RNA concentration¹², and compared with the activity for the RNA from the culture before the medium change.

to the *rc* gene product and/or its synthesis of ppGpp, little is known about the detailed mechanisms involved in controlling the two types of transcription. To what degree does the stringent response exist in eukaryotic cells, which use separate polymerases for the transcription of ribosomal RNA and messenger RNA^{6,7}? We⁷ and others⁸ have shown that in *Saccharomyces cerevisiae* deprived of an amino acid, the transcription of ribosomal RNA is severely inhibited. Ribosomal RNA transcription is also inhibited in cells treated with cycloheximide^{7,9}, but it continues almost normally in cells in which synthesis of ribosomal proteins has specifically been inhibited through a temperature-sensitive mutation¹⁰. We demonstrate here that in cells deprived of an amino acid there is a specific depletion of messenger RNA coding for ribosomal proteins.

The experiments are based on our ability to translate yeast mRNA quantitatively in a wheatgerm extract and to isolate the yeast ribosomal proteins produced¹¹. Total protein synthesis and the synthesis of yeast ribosomal proteins are linearly dependent on added yeast RNA, reaching a maximum at the same RNA concentration¹². Thus, unless a saturating concentration of yeast RNA is added to the wheatgerm extract, the radioactivity in any individual ribosomal protein spot is a measure of the relative amount of mRNA specific for that protein.

Cells were deprived of tyrosine as described in Fig. 1 and at intervals the rates of protein synthesis and ribosomal RNA transcription were determined. The effects of tyrosine deprivation on protein synthesis are complete only after an hour, presumably due to a substantial pool of tyrosine within the cells. The transcription of ribosomal RNA decreases slightly later than protein synthesis and levels off at a rate 15–20% of normal. On the other hand, the template activity of RNA prepared from cells deprived of tyrosine remains almost unchanged for 5 h (Fig. 1). As the half life of mRNA in yeast is between 6 and 30 min at 23 °C (ref. 13), substantial synthesis of new mRNA must continue, as was demonstrated directly elsewhere⁷.

Figure 2 is a one-dimensional polyacrylamide gel analysis of proteins synthesised by a wheatgerm extract in response to RNA from cells deprived of tyrosine. Although most proteins show

Fig. 2 Template activity of RNA from cells deprived of tyrosine. Cell-free translation was carried out with wheatgerm extract using as template RNA from cells deprived of tyrosine for increasing time, as described in Fig. 1. An aliquot was treated with 5% TCA, the precipitate electrophoresed on a 7.5–25% acrylamide gel in the presence of SDS according to the method of Laemmli¹⁴. Protein synthesis inhibition is indicated by the arrows, enhancement by arrowheads.

Fig. 3 Template activity for specific proteins. Aliquots of the cell-free translation described in Fig. 1 were subjected to two-dimensional polyacrylamide gel electrophoresis¹¹, and ribosomal and nonribosomal protein spots were cut out. The $A_1 = (^{35}\text{S}/^3\text{H})_i / (^{35}\text{S}/^3\text{H})_{\text{total}}$ (ref. 11) was determined for each, and compared with the unstarved control. ●, Ribosomal protein no. 5; ▲, ribosomal protein no. 33; ○, nonribosomal protein C; △, nonribosomal protein D.

little change, the synthesis of some is inhibited (arrows) and that of others enhanced (arrowheads). Figure 3 shows a quantitative analysis of the template activity for individual ribosomal and nonribosomal proteins for the experiment described in Fig. 1. It is clear that as cells are deprived of tyrosine, they gradually lose mRNA for these two ribosomal proteins. That this is true of most, but not all, ribosomal proteins is shown in Table 1. Some of the exceptions, such as nos 12 and 14, are also exempt from the coordinate regulation in the *ts* mutants described above¹¹. The values for individual proteins in Table 1 and in other experiments are remarkably uniform between experiments, suggesting that the variation between proteins is due to slight differences in the stability of mRNA and/or regulation of its transcription. Nevertheless, the ribosomal proteins seem to be regulated as a class.

Table 1 Template activity for ribosomal and nonribosomal proteins

Protein no.	Subunit	Relative template activity at 5 h	
Ribosomal proteins		Expt 1	Expt 2
1	L	0.26	0.36
2	L	0.35	0.42
5	S	0.34	0.25
6	L	0.30	0.30
8	L	0.41	0.40
11	L	0.65	0.42
12	S	1.30	0.71
13	S	0.52	0.42
14	S	0.89	0.97
24	L	0.47	0.39
28	L	0.30	0.33
29	L	0.30	0.34
30	S	0.90	0.81
33	L	0.22	0.26
38	L	0.43	0.31
39	L	0.47	0.41
40	S	0.96	0.75
41	S	0.34	0.36
45	L	0.33	0.30
46	L	0.35	0.32
Nonribosomal proteins			
C		0.96	0.98
D		0.82	0.94
E		1.06	0.92
G		1.00	1.26

Template activity for ribosomal proteins and nonribosomal proteins was measured as described in Fig. 3. The values represent the ratio of template activity of RNA from cells deprived of tyrosine for 5 h to the template activity of RNA from unstained cells, for two independent experiments. Experiment 2 is that of Fig. 3. L is the large (60S) subunit, S is the small (40S) subunit.

These results show that in yeast cells deprived of an amino acid there is a parallel inhibition in the synthesis of both ribosomal RNA and mRNA for most ribosomal proteins. The fact that the decline in mRNA activity occurs somewhat later than that of rRNA transcription may be due to the finite half life of mRNA for ribosomal proteins, which at 23 °C is probably 20–30 min^{13,15}. The kinetics in Figs 1 and 3 are consistent with the transcription of rRNA and mRNA for ribosomal proteins being inhibited simultaneously. It seems, therefore, that yeast has a fully coordinated stringent response to the deprivation of an amino acid, which involves ribosomal RNA as well as mRNA for ribosomal proteins, but excludes both tRNA and mRNA for the bulk of the cell's proteins⁷. Although ppGpp has not been detected in such conditions (J. Gallant, personal communication), a search for 'relaxed' mutants and for a regulatory molecule may be useful.

We thank Dr E. Falke for discussions, M. Studeny for technical assistance, and the NSF (PCM75 03938A01), the ACS (NP 72H) and the NIH (P30 CA 13330 and 2P50 GM 19100) for support.

In vivo aminoacylation and 'processing' of turnip yellow mosaic virus RNA in *Xenopus laevis* oocytes

IT is now well established that several plant and animal virus RNAs possess a 'tRNA-like' structure, as they are recognised *in vitro* by many tRNA-specific enzymes. To approach the problem of the possible physiological significance of these structures for the development of the virus, it seemed important to determine whether they are also recognised *in vivo*. The most logical approach would have been to use plant protoplast systems to study the behaviour of viral genomes in the infected cells. However, because such systems are still difficult to control, we decided to use the oocyte system. We describe here how turnip yellow mosaic virus (TYMV) RNA, which can be aminoacylated *in vitro* by valine¹, was microinjected into *Xenopus laevis* oocytes, incubated in the presence of ³H-valine and the RNA charged *in vivo* analysed. We conclude that TYMV RNA, the 3' terminal sequence of which is –CC (refs 2, 3), is aminoacylated *in vivo*. This indicates that the viral RNA is recognised by the oocyte tRNA nucleotidyltransferase and valyl-tRNA synthetase. Furthermore, the TYMV Val-RNA recovered after the *in vivo* reaction is fragmented and migrates between 4S and 5S RNA markers. This implies that (an) RNase(s) split(s) the viral genome, liberating this tRNA-like structure.

Table 1 Aminoacylation of total TYMV RNA, of TYMV coat protein mRNA or of *E. coli* tRNA^{Val} microinjected into *X. laevis* oocytes

Expt	(t)RNA injected	Species	pmol* per oocyte	No. of oocytes injected	c.p.m. per oocyte
1	None		—	40	1,546
	Total TYMV RNA		0.37	40	1,743
	<i>E. coli</i> tRNA ^{Val}		22	7	30,920
2	None		—	51	1,396
	Total TYMV RNA		0.37	53	1,509
	TYMV coat protein mRNA		0.17	56	1,130

TYMV was extracted from infected Chinese cabbage leaves according to Leberman¹². Total TYMV RNA was recovered using the phenol-chloroform-sodium laurylsulphate method^{13,14}. Partially purified viral RNA coding *in vitro* for coat protein (coat protein mRNA) was separated from genomic RNA by chromatography on a Sepharose 6B column. Fully grown oocytes from *X. laevis* females were preincubated for 3 h at 20°C in modified Barth's medium¹⁵ (100 µl per 10 oocytes) containing ³H-valine (31 Ci mmol⁻¹; Amersham) at a final concentration of 1 mCi per ml. They were microinjected¹⁶ with the following substrates in 50 nl of sterile water: 11.2 mg ml⁻¹ of *E. coli* tRNA^{Val} (Sigma), 15.4 mg ml⁻¹ of total TYMV RNA, or 870 µg ml⁻¹ of TYMV coat protein mRNA, and incubated at 20°C in fresh medium containing ³H-valine as above. After 2 and 24 h of incubation for experiments 1 and 2, respectively, the oocytes were washed with modified Barth's medium and stored at -70°C. They were homogenised and the RNA extracted as reported by Gatica *et al.*¹⁷. After ethanol precipitation, the RNA pellets were dissolved in sterile water and stored at -20°C. Aliquots were precipitated by 10% cold TCA, filtered through nitrocellulose membranes and the radioactivity retained measured in the presence of Bray's solution. Further analyses were carried out using the samples from experiment 2, except for the *E. coli* ³H-Val-tRNA^{Val}, which was from experiment 1.

*The pmol of (t)RNA injected are based on molecular weights of 2×10^6 for total TYMV RNA, 0.25×10^6 for TYMV coat protein mRNA and 25,000 for tRNA^{Val}.

To see if TYMV RNA could be charged *in vivo*, *X. laevis* oocytes were microinjected with total TYMV RNA (containing genomic RNA and coat protein mRNA)⁴, partially purified TYMV coat protein mRNA or *Escherichia coli* tRNA^{Val}. After 2 or 24 h of incubation in the presence of ³H-valine, the RNA was extracted from the oocytes and an aliquot used to determine the cold trichloroacetic acid (TCA)-precipitable counts; these are given in Table 1. No significant variation in counts is observed with oocytes injected with total TYMV RNA as compared to control, uninjected oocytes, even after 24 h of incubation. The same is true when TYMV coat protein mRNA is injected. Conversely, incubation with *E. coli* tRNA^{Val} leads to a 20-fold stimulation after only 2 h of incubation.

The fact that no increase in cold TCA-precipitable counts could be detected with the viral RNA preparations can certainly be explained by the low amount of TYMV RNA injected as compared to tRNA^{Val}. Indeed, the charging capacity of total TYMV RNA on a weight basis is about 80 times lower than that of a tRNA (see legend to Table 1).

Because it had not been possible to detect TYMV RNA charging by TCA precipitation, it was necessary to analyse the size of the ³H-Val-oligonucleotides recovered after T₁ RNase digestion of the RNA extracted from the oocytes. This was carried out by paper electrophoresis in 0.5 M formic acid (results not shown) or by thin-layer chromatography (TLC) on polyethyleneimine-cellulose (PEI-cellulose) plates (Fig. 1).

The T₁ digests of TYMV Val-RNA charged *in vitro* reveal the presence of a Val-pentanucleotide (Fig. 1, sample 4) and those of *E. coli* Val-tRNA, also charged *in vitro*, of a Val-pentanucleotide and a Val-tredecannucleotide (sample 6). This agrees with the known sequence of the 3' region of TYMV RNA^{2,5,6} and of the valine-specific *E. coli* tRNAs^{7,8}, respectively.

The endogenous oocyte tRNAs charged *in vivo* (sample 1, see also samples 2 and 3) produce two Val-oligonucleotides of about eight and nine residues, plus a third spot which migrates faster than a pentanucleotide.

The analyses of the Val-oligonucleotides obtained after T₁ digestion of the RNAs extracted from oocytes injected either by total TYMV RNA (sample 2) or TYMV coat protein mRNA (sample 3) showed in each case the presence of a Val-pentanucleotide, demonstrating the *in vivo* aminoacylation of TYMV RNA. This ³H-Val-pentanucleotide is much less intense when the oocytes are injected with TYMV coat protein mRNA than with total TYMV RNA, and this is probably due to a partial degradation of the RNA molecules during the purification procedure.

In sample 2, the Val-oligonucleotides of about eight and nine residues migrate somewhat faster than those in samples 1 and 3, and this is probably due to the presence of salts in sample 2. In samples 1, 2 and 3 (*in vivo* charging experiments) a spot appears that migrates faster than the Val-pentanucleotide. Although this spot is not produced when total oocyte tRNAs are charged *in vitro* (results not shown) by an *E. coli* extract or by a rat liver extract, one cannot exclude the possibility that it corresponds to a tRNA isoacceptor for valine only charged by the homologous enzyme. This supplementary spot was shown not to be due to free valine, Val-AMP or Val-adenosine (data not shown).

After injection of *E. coli* tRNA^{Val} into the oocytes (sample 5), an ³H-Val-tredecannucleotide appears which corresponds to the T₁ digest of ³H-Val-tRNA^{Val}. No spot corresponding to the digests of endogenous oocyte ³H-Val-tRNA is observed. This is due to the fact that the same number of counts were deposited in all cases shown in Fig. 1, and that after injection of *E. coli* tRNA^{Val}, a 20-fold stimulation in cold TCA-precipitable counts

Fig. 1 Separation by TLC on PEI-cellulose plates of the ³H-Val-oligonucleotides obtained after T₁ RNase digestion of *in vivo* or *in vitro* charged (t)RNAs. The *in vitro* aminoacylation with ³H-valine (31 Ci mmol⁻¹; CEA) of unfractionated *E. coli* tRNAs or of total TYMV RNA was carried out as described by Yot *et al.*² using an *E. coli* extract devoid of tRNAs. ³H-Val-(t)RNAs (20,000 c.p.m.) recovered after *in vivo* (see Table 1) or *in vitro* aminoacylation were incubated for 45 min at 37°C in a mixture (15 µl) containing 20 mM sodium citrate, pH 5, 1 mM EDTA, and 0.25 units of T₁ RNase (Sankyo) per µg of Val-(t)RNA. The PEI-cellulose W.R. plates (20 × 20 cm, plastic-backed, with luminescer, Schleicher and Schüll) were soaked in methanol, dried and the digests applied. The plates were developed at room temperature in a stepwise fashion without intermediate drying, using a slight modification of the method of Gupta and Randerath¹⁸; with water to 1.4 cm above the origin; 0.05 M Tris-HCl, pH 6.8, to 4.2 cm; 0.15 M Tris-HCl-8.5 M urea to 7.7 cm; 0.3 M Tris-HCl-8.5 M urea to 10.5 cm; 0.5 M Tris-HCl-8.5 M urea to 14 cm, and finally, with 0.75 M Tris-HCl-8.5 M urea to 16.8 cm. The sheet was dried, fluorographed^{19,20}, and exposed at -70°C using Kodak X-Omat R films. The T₁ digests correspond to the ³H-Val-oligonucleotides obtained from: 1, uninjected oocytes; 2, oocytes injected with total TYMV RNA; 3, oocytes injected with TYMV coat protein mRNA; 4, *in vitro* charged TYMV RNA; 5, oocytes injected with *E. coli* tRNA^{Val}; 6, *in vitro* charged *E. coli* tRNAs.

Fig. 2 Analysis by 10% polyacrylamide-7 M urea gel electrophoresis of the TYMV ^3H -Val-RNA charged *in vitro*. Polyacrylamide gel electrophoresis was a modification of the method of Donis-Keller *et al.*²¹: the sample buffer, polyacrylamide gel and electrophoresis buffer were the same but at pH 7, and the Val-(t)RNA samples (10,000 c.p.m.) were not heated before the run. Electrophoresis was carried out at 4°C and 200 V, and the electrophoresis buffer was constantly recycled. The gel was soaked in 10% cold TCA for 1 h, fluorographed^{20,22} and exposed at -70°C. Marker RNAs were run in parallel and stained with ethidium bromide. 1, Uninjected oocytes; 2, oocytes injected with total TYMV RNA; 3, *in vitro* charged TYMV RNA; 4, oocytes injected with *E. coli* tRNA^{Val}; 5, *in vitro* charged *E. coli* tRNAs. XC, xylene cyanol FF.

was observed (Table 1) as compared to uninjected oocytes. Consequently, the corresponding products from endogenous oocyte tRNAs are not visible.

The T₁ digests of the samples presented in Fig. 1 were also separated by paper electrophoresis in 0.5 M formic acid; the conclusions reached agree with those of Fig. 1, namely, that TYMV RNA is aminoacylated when injected into the oocytes.

TYMV RNA as extracted from the virions terminates at the 3' end by -CC. Thus, a positive response to valine aminoacylation indicates that the RNA is recognised *in vivo* by the oocyte tRNA nucleotidyltransferase as well as by the valyl-tRNA synthetase. Solari *et al.*⁹ reached similar conclusions when testing the aminoacylation of injected tRNA^{Phe} devoid of its 3'-terminal adenosine.

It was important to determine the size of the TYMV Val-RNA charged in the oocytes. To this end, ^3H -Val-(t)RNAs charged *in vivo* (oocytes) or *in vitro* (*E. coli* extract) were analysed by electrophoresis on a 10% polyacrylamide, 7 M urea gel (Fig. 2). Total TYMV RNA charged *in vitro* (slot 1) shows in addition to endogenous Val-tRNAs (slot 1) a Val-RNA band migrating between 4S and 5S markers and corresponding to the tRNA-like fragment of TYMV. In the case of TYMV RNA charged *in vitro* (slot 3), an intense band migrating in the same position appears as well as a series of fainter bands of higher molecular weight. Experiments of *in vitro* aminoacylation of TYMV RNA indicate that, with prolonged incubation, these bands of higher molecular weight give rise to the tRNA-like fragment (S. J. and A.L.H., unpublished results).

The *E. coli* system is known to contain RNase P, a maturation enzyme of tRNAs (ref. 10). Extracts containing this enzyme

have been shown

to split TYMV (Val)-RNA, releasing a 4-5S fragment to the 3' end of the genome (see also Fig. 2, similar enzyme(s) experiments here strongly suggest that (a)

As a further control, the oocyte. 4); a main band corresponding to Val-tRNA was obtained, and similarly by *in vitro* charged *E. coli* tRNAs (slot 5).

The results presented here on the structure of a viral RNA is to demonstrate that the tRNA-like structure of a viral RNA is 'processed' *in vivo*, liberating its tRNA-like structure.

Even though these results were obtained using an animal cell, it is likely that similar conclusions would be reached with a plant system. As plant cells are not yet accessible with a plant oocyte might constitute a useful material for such studies, the physiological role of tRNA-like structures in the study of the first place, it is tempting to speculate that the 4-5S RNA fragment formed *in vivo* plays a part in the infected cell by inhibiting, for example, a factor involved in protein synthesis. It is not unlikely that in the infected plant a part of the viral genome could be sacrificed for the formation of such an inhibitor. Indeed, preliminary results (S.J. and A.L.H., unpublished observations) with plant extracts indicate that they also contain (an) enzyme system(s) capable of liberating the tRNA-like structure from TYMV RNA.

We thank Drs H. Chantrenne and F. Chapeville in whose Departments these studies were carried out for their suggestions, C. Benicourt and M. Katouzian for discussions, A. Mazabraud for oocyte tRNAs, C. Gualerzi for rat liver extract, S. Astier-Manificier and P. Cornuet for infected Chinese cabbage leaves, C. Benicourt for partially purified TYMV coat protein mRNA and D. Hayes for *E. coli* 5S RNA. S.J. is recipient of a Stipendium from the 'Délégation Générale à la Recherche Scientifique et Technique'. G.H. and G.M. are 'Chercheurs qualifiés' of the Belgium 'Fonds National de la Recherche Scientifique'. Part of this work was supported by the 'Actions concertées' from the Belgium State.

Relationship of proteable surface area thermostability to a

THE pH of an unbuffered protein solution subjected to a continuous temperature increase usually exhibits a single inflection point associated with the cooperative thermal denaturation of the native conformation. Bull and Breese² have used this procedure to determine the midpoints (T_m) for 14 proteins and have found that this parameter is the principal determinant of protein thermostability. We report here our study of 30 additional proteins, selected because of their homogeneous form. With this expanded data base, solvent-accessible surface area was found to result in a better correlation with protein thermostability.

The apparatus used is similar to that described by Bull and Breese², a Radiometer model 25 pH meter, a Radiometer GK 240C combination electrode, a model 425C (Yellow Springs) bridge and thermistor probe, and an Omniscribe dual pen recorder (Houston). Individual protein solutions of about 2 mg ml⁻¹ concentration were dialysed against 0.2 M KCl before use. The protein solution, pH electrode, thermistor probe and a small magnetic stirring bar were inserted into a jacketed vessel surrounded by a grounded wire screen. The temperature of the protein solution was continuously varied by a circulating water bath programmed to increase by 0.83°C per min. Observed pH values were corrected for temperature as described by Goodno *et al.*³.

The T_m values for 30 proteins are listed in Table 1 in increasing value. Each protein preparation used exhibited a single

Coomassie blue staining component when examined by polyacrylamide gel electrophoresis in the presence of detergent, and a single $\Delta pH/\Delta T$ discontinuity over the temperature range 30–90°C. The single exception to this is the preparation of the S1 fragment of myosin, which contains a major component of molecular weight 9.3×10^5 . Scanning calorimetric measurements indicate that this component has a T_m of 43°C. The T_m values listed are the highest values measured in the pH range 4–9. Those listed in Table 1 for nine proteins (6,7,21,22–25,27,30) of the 10 proteins studied in common with Bull and Breese have T_m values agreeing with those previously reported indicating that our execution of the $\Delta pH/\Delta T$ procedure is appropriate. However, our measurements do not support the correlation between T_m and average residue volume (V_R) reported by Bull and Breese². In contrast to their correlation coefficient of +0.96, we find a value of -0.02. Similarly, in contrast to their correlation coefficient between T_m and hydrophobic index of +0.62, we find a value of -0.01. We conclude that the previously reported strongly positive correlation coefficients resulted from examination of a limited number of proteins and do not necessarily reflect any fundamental principle of protein stability.

In searching for an alternative explanation for the observed variation in protein thermostability, we noted that T_m exhibited an imperfect inverse trend with polypeptide chain length. As the ratio of surface to volume for globular proteins decreases with chain length, we have related the observed T_m values to the fractional area of the polypeptide accessible to the solvent. The total surface area of a denatured polypeptide chain, A_t , was calculated from the relationship⁴ $A_t = 1.44M$, where M is the molecular weight of the protein; the solvent-accessible surface area of an individual protein globular domain was calculated using the relationship⁵ $A_s = 11.116M^{2/3}$, and the accessible surface area of a globular domain in a dimeric or square planar tetrameric polymer of identical globular domains was deter-

Table 1 Protein parameters

Code	Protein	Source	pH	T_m	V_r	Φ	$\log M_s$	n
1	Myosin S1 fragment	Rabbit muscle	6.83	43 ± 1	87.6	788	4.97	2

Columns headed by the terms or symbols, pH, T_m , V_r , Φ , $\log M_s$ and n refer to the pH at which the T_m was observed, the T_m measured by the $\Delta pH/\Delta T$ procedure, the average residue volume, the hydrophobic index, the log of the polypeptide molecular weight and the number of polypeptide chains present in the native protein, respectively. The hydrophobic index was calculated as described by Bigelow¹¹.

Fig. 1 Relationship of fractional polypeptide area accessible to solvent, A_s/A_t , and protein thermostability, T_m . A_s is the polypeptide surface area in $\text{\AA}^2$ accessible to the solvent in a native globular protein, A_t the total accessible surface area of a denatured protein, and T_m the midpoint of the thermal denaturation detected by the $\Delta pH/\Delta T$ procedure. The open circles indicate monomeric proteins and the filled circles polymeric proteins. The number associated with each experimental value indicates the identity of the protein as encoded in Table 1. The lines represent least-squares analyses of the values for the monomeric (except for proteins 20 and 25) and the polymeric proteins.

mined using the factors⁵ 0.857 and 0.714, respectively, to account for the surface lost in the monomeric unit by polymerisation. As seen in Fig. 1, the values for the 30 proteins seem to cluster about two linear relationships with a common slope, one relationship being populated exclusively by monomeric proteins and the second principally by polymeric proteins.

The slopes of these lines suggest that increasing the internal area of these proteins at the expense of surface area decreases the thermostability in the temperature range considered. As hydrophobic index and percentage apolar atoms are independent of polypeptide chain length, and as polar atoms are preferentially located on protein surfaces, it follows that more polar atoms, particularly those of the peptide backbone, must be internalised as the fractional surface area is diminished. Such internalisation of polar atoms in contrast to apolar atoms presents a problem, for burial of a polar atom not complementarily hydrogen bonded in the internal apolar environment is energetically unfavourable. We propose that as more polar atoms need to be internalised to fold longer polypeptide chains into globular units, the probability of noncomplementary burial increases, leading to the decreased thermostability indicated in Fig. 1. In the case of burial of peptide backbone polar atoms, it should be noted that the amount of secondary structure, a common method to pair these atoms complementarily, is independent of chain size. The relationship exhibited by the monomeric proteins predicts that a polypeptide with a molecular weight $>60,000$ folded into a single globular domain would be unstable when present in an organism maintained at 37°C . Fisher⁶ has suggested that large polypeptide chains would be stabilised by forming asymmetrical structures, thus increasing their surface to volume ratios.

Alternatively, the results shown in Fig. 1 suggest two alternative ways in which the thermostability of larger polypeptide chains can be enhanced. One involves using globular surfaces to contribute to conformational stability through association of globular subunits to form polymers. Analysis of subunit interfaces suggests that polar complementarity provides the selectivity while apolar interactions provide the added stability for these inter-subunit interactions. The relationship exhibited by the polymeric proteins in Fig. 1 suggests that polypeptide chains with molecular weights up to about 160,000 would be stable at 37°C provided that such chains fold into globular units and that the globular units polymerise. This limitation would encompass the polypeptide chain lengths of all globular polymeric proteins⁸. The results shown in Fig. 1 also suggest a second way to increase the thermostability of larger polypeptide chains, namely, folding a single chain into multiple globular domains. A case in point is the apparent enhanced thermostability of phosphoglycerate kinase, protein 9. The crystallographic structure⁹

of this protein demonstrates that its single polypeptide chain folds into two globular domains of nearly equal size, with minimal interdomain contact; this conformation would increase the fractional surface area relative to folding into a single globular domain and accordingly increase thermostability. Analysis¹⁰ of the sequence of serum albumin suggests that this protein folds into three globular domains of closely related sequence, probably the result of fusion of duplicated structural genes. The position of the T_m for serum albumin, protein 20 in Fig. 1, suggests that its structure resembles that of a covalently linked polymeric protein. The position of the T_m for ovalbumin, protein 25, in Fig. 1, suggests that its relatively large polypeptide chain is also folded into more than one globular domain. Unfortunately, no sequence or crystallographic information is yet available for ovalbumin to validate this suggestion.

In presenting our analysis of thermostability in terms of the size of globular domains and polymerisation of domains, we recognise that other considerations such as the presence of disulphide bonds, ligation of strongly bound metal ions, haem moieties and other cofactors, packing densities, and intra-surface interactions will also influence thermostability. Indeed, such considerations may be partly responsible for the scatter of the values about the linear relationships considered in Fig. 1. We also recognise that the inverse A_s/A_t dependence on T_m for globular proteins produces an absurd extrapolation, namely, that the most thermostable protein would have no buried area. Clearly, other considerations must limit this relationship. However, it seems to extend to include pancreatic trypsin inhibitor, which has a A_s/A_t value corresponding to a T_m of 111°C , as no $\Delta pH/\Delta T$ discontinuity could be detected for this protein at temperatures up to 98°C . Although, as more information becomes available, our analysis of thermostability may suffer the same fate as the average residue volume correlation, a cursory review of thermal inactivation measurements for a variety of enzymes suggests that size of globular domains and polymerisation are critical to protein thermostability.

This investigation was supported by USPHS research grant GM-13215 from the Institute of General Medical Sciences.

Volatilisation of methylmercuric chloride by hydrogen sulphide

TREATMENT of methylmercuric chloride with hydrogen sulphide in aqueous solution has been shown by Rowland *et al.* to result in volatilisation of mercury¹. The volatile product was not identified but was considered to be a 'volatile sulphur compound of methylmercury'. Volatilisation of mercury and concurrent lowering of the pH of the aqueous solution¹ can be explained by formation of bis(methylmercuric) sulphide (A).

This reaction has previously been carried out in ethanol^{2,3}. The foul odour of A (ref. 2) indicates that it is volatile, even though it is a solid at room temperature. Loss of mercury caused by ammonium sulphide¹ can also be attributed to formation of A.

The reduced effectiveness of this reagent compared with hydrogen sulphide¹ can be explained by the simultaneous occurrence of reaction (3).

Reactions analogous to (2) and (3) have been observed between MeHgBr and Na₂S (refs 4, 5).

Absorption of the volatile mercurial by alkali¹ can be attributed to formation of the known⁶ *tris*(methylmercuri)oxonium hydroxide (B) (contrast with doubtful existence of MeHgOH⁶).

The ionic character of B would explain the failure of the base-soluble species to undergo chromatography¹. Although chloride ions, from absorption of volatilised HCl, would also be present, the equilibrium (5) would lie well to the left. However, extraction with toluene would remove the non-ionic methylmercuric chloride and drive the equilibrium to the right, explaining recovery¹ of MeHgCl by this method.

The volatilisation of methylmercury could also be explained by formation (6)

of MeHgSH (reported preparations^{7,8}), and reactions (2) and (4) could be modified to accommodate this. However, reaction (6) has not previously been demonstrated, whereas there is precedent for (1)–(3)^{2–5}, hence A is preferred as the source of volatility. Since A is unstable, decomposing by (7)², dimethylmercury and mercuric sulphide would probably be the ultimate products from MeHgCl and H₂S in an environmental situation.

World's oldest animal traces

BIOLOGISTS and biogeologists would like to know when multicellular animal life began. Well authenticated records show that it was present by ~680 Myr ago, but older records have not withstood scrutiny. Clemmey's report¹ of metazoan burrows from 1,000 Myr old rocks in Zambia therefore excited great interest. I have examined the specimens and seen Clemmey's coloured slides of the outcrops, and this examination and subsequent research led to a different conclusion from his. The Zambian burrows are undoubtedly metazoan and indigenous to the sedimentary deposits in which found, but they are of post-depositional origin and related to a geologically recent surface. Evidence for this conclusion rests in the bleached, saprolitic nature of the host rock and the contrasting red and pink banded burrow-fillings, containing rounded, ferromanganese-coated quartz grains that are much larger than particles of the adjacent matrix. Such characteristics suggest introduction of burrow-filling material from a relatively recent lateritic weathering surface.

Further study and inquiry among students of the social insects led to the additional conclusion that Clemmey's burrows are the work of termites, digging through and parallel to the softer layers of the steeply dipping saprolitic rock to obtain water for humidification of their nests. From publications and correspondence with termite specialists M. Lüscher, Ch. Noirot, M. L. Roonwal and W. A. Sands, I found that termites do burrow to depths of 70 or more metres to reach the water table, that they burrow preferentially in the least resistant parts of the rock, and that they backfill unused burrows with surface matter producing laminated burrow-walls and a banded 'spreite' pattern like that illustrated by Clemmey. His observation that the burrows are parallel or nearly so to the bedding, and that they favour particular stratigraphic levels, would be consistent with descent along the softer of the steeply dipping strata of the Zambian Copperbelt.

The above comments apply mainly to burrows of the type of Clemmey's Fig. 1. The oval profile, pinching and swelling along their lengths, and terminal branching of such burrows is also termite-like. The bioturbation of his Fig. 2 may represent a zone of termite foraging or collapse. Specimens like his Fig. 4 (with a hollow interior) resemble the covered passageways through which termites cross lighted areas.

CLEMMY REPLIES—I agree that the burrows I described are only obvious after weathering, but this is a feature shared by much of the internal fabric of rocks and in this case has an explanation. The red and pink banding results from weathering of the microchemical/mineralogical differences between bioturbated and non-bioturbated sediment. Within the burrows it reflects the differences between sediment passed around the body or through the gut of the animal and such differences are to be expected in bioturbated sediment¹.

The burrow, as a microreducing environment, attracted the precipitation of iron sulphides, which ideally would be more concentrated in the zones of the bioturbated sediment richest in organic matter. On weathering the ferrous iron is oxidised to the ferric state and hence the

red and pink shades. The country rock depending on its iron content weathers cream, brown, or pink. Within the bioturbated sediment and sometimes in the country rock are pools of authigenic quartz such as may be formed when silicates are breaking down under biogenic attack or during weathering and are releasing large amounts of silicic acid. These are the 'quartz grains' referred to by Cloud.

If the burrows were made by termites, why did those making type A (ref. 2) burrows live only above the 2 m of strata at the base of the Orebody Member whilst the succeeding 2 m are characterised only by those making type B burrows²? And why is the unit containing the burrows overlain by hundreds of metres of identical lithologies which show no signs of bioturbation. I believe that the burrows are not those of termites nor are they lithologically controlled, but they are paleofacies-controlled. The transition type A to type B burrows reflects the transition from intertidal to lagoonal/lacustrine sedimentation, as indicated by facies studies³.

Total destratification, such as indicated by my Fig. 2 (ref. 2), produces a swirled fabric in the rock; this is explained only by invoking contemporaneous sedimentation and bioturbation. For while small tunnels of termite origin are at least conceivable, complete fluid mixing over a thickness of several centimetres is not. This fabric implies that the medium undergoing bioturbation was granular and wet.

The idea that type B burrows represent covered passageways is not feasible. The burrows are an integral part of the rock, are not confined to exposed bedding surfaces and can be revealed by excavating the strata. They have pellet-formed walls which may show disintegration at the burrow termination into equidimensional pellets. Again these are part of the rock and not surficial features.

As far as it is possible to tell, the burrows (unequivocally metazoan according to Cloud) were formed contemporaneously with the sedimentation of the containing units about 1,000 Myr ago.

No paradox in the control of energy intake

AS Rothwell and Stock¹ note their results refute the notion that a particular size of energy store precisely controls energy

intake in rats. Other reports²⁻⁴ agree with this. However, contrary to what is claimed, their results do not necessarily reveal a paradox or physiological enigma in the control of energy intake in the rat. They are clearly compatible with the theories of Kleiber⁵, Adolph⁶, Ugolev⁷ and Booth⁸, in which energy metabolism controls feeding and the energy store is only one component in the feedback system. Rothwell and Stock state that our model⁹ has yet to include effects of body energy increments. On the contrary, in a publication which they cite¹⁰, and elsewhere¹¹, we have included a representation of effects of energy store size on intake through energy metabolism. We also emphasised that although the energy store may settle at a particular size¹¹⁻¹³, there is no privileged size either achieved or used as a homeostatic set-point. In these simulations the precision of defence and (if a specific size is maintained) the value defended depends on a compromise between the small but persistent graded effect of store size on metabolism and all the other dietary and endocrine conditions affecting metabolism.

Rothwell and Stock also state that it is difficult to conceive how such a model could explain an increase in fat deposition rather than a decrease in intake when energy supply is in excess of requirements. However, our model probably provides several ways of increasing efficiency without altering intake. For example, a change in regimen might divert a higher proportion of absorbed energy into fat, while also reducing the faecal excretion of energy or the thermic effect of feeding. All these effects would be liable to increase the size of the energy store in the model. The extra metabolism from the increased retention of energy intake would help reduce intake, and the extra diversion after absorption would help to increase it.

The importance of Rothwell and Stock's data lies in the questions raised as to the exact mechanism(s) by which dietary changes can alter the relations among the processes of utilisation, storage and intake. Quantitative simulation is of similar importance.

ROTHWELL AND STOCK REPLY—We apologise to Booth and Toates if we have neglected those aspects of their feeding model that take into account energy storage. Nevertheless, we were well aware (and said so) that the increased fat deposition of our animals results from an increased metabolic efficiency (almost certainly due to a decreased thermic effect of feeding), thus providing a larger fraction of total ingested energy available to metabolism. According to Booth and Toates, this excess energy would either reduce total energy intake or, if diverted to fat storage, help to increase intake. In fact, we found that total energy intake remained at precisely the same level as that in the free-feeding control animals.

We would also suggest that an energostatic approach fails to account for the differences between the two types of energy load used in our experiments, that is, fat and Complan. If one accepts Booth's proposal¹ that it is the availability of energy that determines intake, it is logical to assume that isoenergetic stomach loads will have similar effects on voluntary energy intake. In our experiments, however, rats tube-fed 34% of normal intake precisely compensate for the load when it is a balanced nutrient mixture, but over-eat by 15-16% when the load is comprised of fat. This suggests that an energostatic approach may be too simplistic and, since our original letter was published, Savory has written to us supporting this view. He obtained very similar results to ours by feeding quail with diets of varying energy density², and one of his conclusions from this work was that "... differences in energy expenditure were not balanced by differences in nutrient intake, so perhaps the quail were regulating food intake to meet their requirements for some dietary component other than energy".

There are many attractive aspects of the energostatic model of Booth and Toates, and we regret that they did not take advantage of their computer simulation to substantiate the claim that our results are compatible with their feeding model. We hope that they will do so and if necessary, as we suspect it will be, make appropriate alterations.

Induced suction and lithospheric plate pull

SHOEMAKER¹ proposes to explain the driving force of plate tectonics as 'induced suction' by the low density sediments in the trench. However, his calculation, which is based solely on fluid statics, does not tell us what the energy source for the motion is, neither does it tell us anything essentially new about subduction dynamics.

To illustrate this, consider an experiment in which a high viscosity fluid is flowing steadily over the edge of a horizontal table. The fluid which has just passed over the edge responds to the unbalanced vertical force of gravity, and this force is 'communicated' to the rest of the fluid by means of a horizontal pressure gradient (that is, the upper surface of the fluid is no longer horizontal). A statics calculation of the type made by Shoemaker would demonstrate that the table edge provides 'suction', but this obscures the fact that the cause of the motion is the vertical force of gravity. The essentials of the argument still apply if the rheology is more complicated.

In the plate tectonics context, the value Shoemaker obtains for the 'suction' is nothing more than the downward force on the subducting slab, presumably caused by gravity². Trench depression can be predicted by a dynamical calculation³, and the accumulation of sediments at the trench is an effect of plate motion, not a cause.

D. J. STEVENSON

2. Stevenson, D. J. & Turner, J. S. *Nature* **270**, 334 (1977).
3. McKenzie, D. P. *Geophys. J. R. astr. Soc.* **18**, 18 (1969).

SHOEMAKER REPLIES—Induced suction¹ is a consequence of the combination of two conditions being satisfied by the subduction process: first, that the fluids or materials above and below the subducting plate have different densities and second, that the subducting plate bends beneath the overriding plate in contrast to the idealised situation where it passes from the horizontal to the downward dipping state through a sharp corner². The force of induced suction is not the downward force of the subducting slab nor is there any direct connection between these two forces. There is an obvious indirect connection in that the downward force of the subducting slab has a major influence in creating the downward bend which causes the induced suction.

The major energy source for plate motion may be downward pull of the subducting slab; it might be something else. However, any consideration of

energy is immaterial to the argument presented for 'deriving' the existence of induced suction. The argument was based on equilibrium which has equal validity with energy principles.

There is no connection between the example of a highly viscous fluid flowing over the edge of a table and induced suction. The 'communication' between the downward flowing fluid and the horizontal flowing fluid on the table is provided by the table edge; the horizontal component of the force exerted by the table edge upon the fluid pulls the fluid along the table. This is not induced suction. Moreover, the fluid will certainly flow if, for example, there is air above and below the fluid 'slab'.

Circadian variation in immune response to oxazolone

FACHET AND ANDO¹ suggest that cellular and humoral responses to oxazolone are under the control of *H-2* genes. Their evidence for the control of cellular immunity was based on the differences between inbred and *H-2* congenic strains of mice in the magnitude of the delayed hypersensitivity response to oxazolone. This was measured in the ears of sensitised mice as the difference in ear thickness measured immediately before and 24 h after challenge. Using this method, we have demonstrated in rats that the magnitude of the maximum immune response depends on the time of day at which oxazolone is applied to the ears². Subsequently, we have shown that there are circadian variations in the skin response to the injection of purified protein derivative in man³. It seems that the time of day at which the antigen is encountered influences the magnitude of the delayed hypersensitivity response.

Most investigators carry out experiments at the same time of the day. We would welcome an assurance from Fachet and Ando on this point, for if their experiments were not standardised to one time of challenge for all the mouse strains, this affects the interpretation of their findings. Additionally, if the oxazolone challenges were given over a long time span within a single day this might affect the results adversely, as the maximum observed response to challenge with oxazolone at 10.00 in the rat is over eight times the minimum response at 16.00.

Data on the time of challenge and the lighting regimen of the animals are not available in the paper from the Hungarian Unit which therefore does not contain sufficient details for the experiments to be repeated, surely a prerequisite of any scientific publication.

Biological rhythms influence many cell-mediated and humoral immune processes with effects which are often of a high order of magnitude. Our recent finding (unpublished) that the delayed hypersensitivity response to oxazolone can be manipulated by altering the lighting regimen of the animals is a further demonstration that the basic principles of chronobiological experimentation need to be introduced immediately into immunological studies.

3. Cove-Smith, J. R., Pownall, R., Kabler, P. A. & Knapp, M. S. *Br. med. J.* **2**, 253–254 (1978).

FACHET AND ANDO REPLY—The points raised by Pownall *et al.* are of interest and we make the following comments. All experimental mice of the *H-2* congenic strains used were sensitised and their delayed-type hypersensitivity (DTH) to oxazolone was tested between 09.00 and 11.00. The same timing of experimental procedures was applied when the DTH to oxazolone was tested in a larger number of animals of the same strain and in mice of other inbred mouse strains. The same conclusion was reached concerning the effect of genes within and outside the *H-2* complex. A single strain has not been independently tested; a series of different strains only has been investigated and used for comparison¹.

Within the scope of our experiments we found no diurnal variation in responsiveness on testing *H-2* congenic mouse strains with oxazolone but it well might occur in different conditions.

Reading the isotopic clocks If you need age determination come to the experts

For the reliable data and custom service that your research demands, come to Teledyne Isotopes.

In 1955, we pioneered in age determination...and that pioneering spirit prevails today. We are the only commercial laboratory offering all major age determination techniques to the world wide geological community:

• C¹⁴ • Rb/Sr • Pb/Pb • K/Ar • U/Pb

Reliability of data is assured through:

- Sample analysis done in modern, efficient labs
- Inter-calibration with major university and government labs
- Use of N.B.S. standards and other internationally recognized reference materials

For all your age determination needs, contact the experienced company.

Seed Pathology Volumes 1 and 2

Paul Neergaard

This is a unique and comprehensive compilation of the most recent data on the subject, brought together by an internationally recognised authority. It is the first book in this field and it is thoroughly up to date.

Paul Neergaard gives a comprehensive survey of research and current concepts relating to seed-borne diseases, the methods used for their identification and control, the mechanics of their transmission through seeds, procedures for laboratory seed testing, and the risk assessment of crop losses due to seed-borne diseases. The book will have a wide application both as a university textbook and as a practical guide and reference work for those involved in almost any sphere of the subject.

Progress in Liquid Physics

edited by **C.A. Croxton**, *Department of Mathematics, University of Newcastle, New South Wales, Australia.*

The most recent major reviews have outlined the essentially sound statistical mechanical foundation of the physics of simple liquids as it stood in the mid-sixties. Since then, significant advances have been made into more difficult and controversial fields, in particular quantal and critical systems, irreversibility, transport phenomena, phase transitions, molecular and polymeric systems, liquid crystals and the role of triple effects. These and other topics are discussed in this collection of review papers. The volume not only attempts to consolidate existing knowledge and understanding but also focuses attention on some of the major outstanding concepts and difficulties which remain unresolved. The book also indicates the development of the subject of liquid physics away from simple fluid systems towards new applications in adjacent fields.

Introduction to Liquid State Physics

by **C.A. Croxton**, *Jesus College, Cambridge.*

This book was written in the belief that the theory of liquids is now ready for dissemination on to a wider and more general audience — to chemists, metallurgists, biophysicists and engineers, not to mention the non-specialist physicist who also needs to know something of the liquid state. Short accounts are presented of irreversibility, phase transitions and transport phenomena, liquid metals and liquid-crystal systems. Inevitably, some selection has to be made, and therefore the more complex molecular systems such as glasses, water and liquid mixtures could not be included.

The equilibrium theory of simple fluids is dealt with at length, together with the statistical thermodynamics of the free liquid surface, and extensive illustrative use is made throughout of the computer simulation schemes which are now central aids in the theoretical development of the subject.

Introductory Eigenphysics

An Approach to the Theory of Fields

by **C.A. Croxton**, *Jesus College, Cambridge.*

This book gives a physical introduction to the mathematical treatment of a large number of problems taken from physics, geophysics, astronomy and chemistry. Emphasis throughout the book is on the physical basis of the problems discussed, the mathematical background is relegated to a series of appendices so as not to interfere with the physical development. Unlike other treatments which suffer from a surfeit of mathematical rigour at the expense of physical understanding, in this approach the mathematics is regarded firmly as a tool of the physics. It is no coincidence that so few differential equations describe so much physics, and in the book the author fully exploits this unifying basis of the subject in an attempt to break down the conventional division between quantum and classical mechanics, between physical optics and electron scattering, or between electrostatics and aerodynamics. Supplementary problems are given at the end of the chapters.

"There are many interesting exercises for the reader... I do, however, warmly recommend the book to teachers."

Introduction to Liquid State Chemistry

by **Y. Marcus**, *Department of Inorganic and Analytical Chemistry, The Hebrew University, Jerusalem.*

This introduction to liquid state chemistry applies the tools of statistical mechanics and thermodynamics to the equilibrium properties of liquids and liquid mixtures, so that reactions and interactions phenomenologically described can also be understood, and made the basis for predictions regarding systems not yet studied. Non-polar liquids, electrolyte solutions, molten salts, non-aqueous solvents, and liquid metals and alloys are brought together in one volume and discussed from a unified point of view, based on common models.

Rationality and actions

A Rational Animal, and Other Philosophical Essays on the Nature of Man. By Anthony Flew. Pp. 245. (Clarendon/Oxford University Press: Oxford, 1978.) £5.95.

THE attempt to demonstrate on *a priori* grounds that natural science can never fully explain human behaviour has been a fashionable parlour game amongst philosophers for some time. This question—and associated problems hinging on the nature of freedom of choice and rationality—is addressed by Professor Flew with somewhat more caution and subtlety than has been displayed by many of his predecessors. Each of the essays of which *A Rational Animal* is composed attacks the views of one or more other thinkers: the targets range from Hume to Lenin, and one cannot help feeling that many of them, like Skinner and Freud, were so philosophically naive that they do not require the weight of artillery that Anthony Flew brings to bear. Moreover, his method of proceeding has the serious disadvantage that amidst the smoke of battle, it becomes difficult to discern the position occupied by the author himself. One longs for a clear statement of his own views, and if in what follows I have misinterpreted him, he is at least partly to blame.

He bases much of his argument on our knowledge that we are free to choose: whenever we perform a voluntary action, we know that we could always have acted otherwise had we so chosen. He takes this alleged fact to be irreconcilable with Laplacean determinism which proposes that each state of the Universe is necessarily caused by its antecedent state. The fact that we can make voluntary movements implies that "What there certainly cannot be . . . is an unbroken chain of sufficient physical causes stretching back indefinitely. It would therefore seem that the central nervous system must either be or contain an apparatus of which the total input does not contingently necessitate every element of total output." He acknowledges that this suggestion is made reluctantly and elsewhere he seems to write as though there were no need for this drastic solution, which implies that the matter in our brains

obeys different laws to those currently thought to hold in inanimate matter. As has often been noted, the invocation of Heisenberg's uncertainty principle is of no help as choices are not made at random and therefore cannot themselves be determined by random events at the quantum level.

Flew's own arguments do not in fact seem to necessitate his conclusion. It no more follows from the fact that we feel free to choose that we are free to choose (in the sense that our choice is not determined by the state of our brains) than it follows that someone who is convinced he can grow wings can grow wings. Moreover, to believe that someone might have chosen differently is surely not inconsistent with believing that he would only have done so had he been in a different antecedent psychological state. This is not to deny the difference between voluntary and involuntary acts. It could be argued that we feel free to choose because we have no way of knowing with certainty what we will do until we decide to do it: in order to know in advance, we would have to simulate at time A our state at time B, and the possible effects of undertaking this simulation at time A on our state at time B could not be included in the simulation itself.

Flew concludes that human actions can never be explained and predicted by physiology: he is correct, but for the wrong reasons. We can no more explain human activity in terms of goings-on in individual nerve cells than we can explain how a computer program works in terms of transistors

To understand how any organised system of matter works, we must develop concepts appropriate to that kind of system. We can understand and predict the hunting behaviour of a system incorporating negative feedback only in terms of control theory not in terms of previously existing physical concepts. Similarly, the scientific explanation of behaviour requires the development of concepts appropriate to understanding the organisation of the brain in relation to the external world: such concepts may not be physical or even physiological, but in as far as they are both precise and render human actions intelligible in a rigorous way, they are nonetheless scientific. Nor does the need to evolve such explanatory concepts suggest that behaviour is undetermined any more than the fact that computer programs cannot be understood in terms of transistors suggests that the outcome of running a program is undetermined.

A small beginning has been made towards developing the requisite explanatory conceptual system within the disciplines of cognitive psychology and artificial intelligence, and it is a pity that philosophers who write about rationality and actions do not examine these disciplines rather than castigating psychoanalysts, who are not scientists, and physiologists, who work at the wrong level of abstraction to be in the business of explaining human actions. □

Stuart Sutherland is Professor of Experimental Psychology at the University of Sussex, UK.

Commissure-section studies

The Integrated Mind. By M. S. Gazzaniga and J. E. LeDoux. Pp 168. (Plenum: New York and London, 1978.)

THE rarity of certain kinds of neurological condition is well recognised. Any investigator who obtained access to more than one case of visual or tactile object agnosia or more than one case of cortical blindness or achromatopsia in a lifetime would count himself lucky indeed.

Surgical brain bi-section falls into a related category. Those of us who work outside of the USA will never have the opportunity to examine such patients (except by visiting the USA), because only in America have the fibre pathways connecting the cerebral hemispheres been surgically divided for the relief of epilepsy. Three separate major series (and one smaller series) of commissure-sectioned patients exist. The earliest patients were investigated before modern and subtle tests of brain

—behaviour relationships had been devised. The next (Californian) series is associated with the names of R. W. Sperry and J. Bogen. These patients were carefully studied after exceptionally radical commissure-section; but, regrettably, only a proportion of the patients have been described in the literature. The most recent (New England) series is smaller in number and the patients underwent less extensive neurosurgery.

Michael Gazzaniga, the senior author of this book, has a unique advantage: personal experience of both the Californian and New England series of patients. In addition, he is the originator of many important experiments on 'split-brain' monkeys, and he described some of the earlier findings in 1970, in his book *The Bisected Brain*. In the present book we are brought up to date with recent findings from the New England series. The intention is to "... reestablish a basic, sober framework for considering studies on cerebral commissurotomy", as a counter to "... a barrage of popular and overdramatized accounts ... largely written by people who had never seen a patient" (p6).

Will the reader (if he is not put off by the title of the new book, or by the statement on p1 that "The corpus callosum, the largest fiber tract in the human brain, contains over 200 million neurons ...") find what is promised? Sadly, no. The majority of observations reported in the book have already been published in the journals. There is no systematic attempt to group the

observations by the extent of surgery, by the duration or amount of pre-surgical pathology, or by the length of time since surgery at the time of testing. Indeed, a large part of chapter 3 is based on the performance of a single patient (P. S.). Yet we read (p85): "In contrast to all the other patients examined in both series is case P. S.", in whom "... we observed an incredible range of language skills in both hemispheres ...". Certainly, the observations forming the basis of chapter 3 were non-linguistic, but no reasons are given why they were not confirmed on other more typical patients from either series.

And yet, in another framework, the book can be recommended. It is essentially an account of the authors' wide-ranging views on such topics as the origins of lateral asymmetries, the role of language, the basis of intelligence and consciousness, the relationship between perception, imagery and memory, and many more such issues. Most of the opinions are original and provocative; and as opinions they are well argued. In due course adequate evidence to support these opinions may be forthcoming. Meanwhile, the book will serve as an intellectual stimulus to a wide range of neuroscientists who are accustomed to making only painfully slow progress in their own laboratories or clinics: given an "integrated mind", what limit is there to our theorising?

G. Ettlinger

G. Ettlinger is Professor of Neuropsychology at the Institute of Psychiatry, University of London, UK.

of what is, as FOE indeed rightly stress, an international common property resource, is not only unjustified but is dangerous. Not only do Soviet fleets operate under significantly different economic parameters, but, as again the FOE stress elsewhere, the USSR has much to gain from any curtailment of solely private capitalistic exploitation.

Overall, the book is fairly good value as it is full of the sort of data and arguments that anyone interested in whales would want to see. It suffers from being an update of a 1975 version, which was an update of the 1972 original. By now it has had a total of 17 authors, and accordingly the deliberately simple style is now patchy, frequently staccato and occasionally irritating. Presentation of the data is generally satisfactory, although some still refers only to 1974-75 which is perhaps disappointing. The few illustrations are rudimentary, but the bibliography is appropriate for the context. The stated objective of the book is to spread information to a wider public, and in this it is likely to succeed. Those in a position to make influential decisions, however, will want to study elsewhere too.

Michael Dunn

Michael Dunn is Principal Lecturer in the Marine Resources Research Unit at Portsmouth Polytechnic, Portsmouth, UK.

Whale primer

Whale Manual '78. Friends of the Earth. Pp. 152. (FOE: 9 Poland Street, London, 1978.) £2.

WHALES are by now a well established *cause célèbre* of the conservation movement, popular on television, and almost universally admired for their benign dispositions and mournful singing. So it comes as something of a jolt to digest the idea that whales could produce a sustainable 2 million tonnes of protein annually (some say), worth perhaps some \$690 million with present prices and utilisation patterns. This little book may help to provide the information to help develop a balanced view on whales and their management, although it remains an enigmatic subject in a manner in which the management of herrings or anchoveta is never likely to be.

In many ways this book is quite excellent. It is ideal as a brief, fact-filled primer on whales and the man-

agement thereof, as long as one accepts that the authors have a (tenable) point of view which significantly colours the text. Not that the contents exclude other people's views, but they are dealt with somewhat erratically. For example, there is some lack of understanding of the reality of economic life, allied to a consistent undertone that, really and truly, whales ought not to be considered as a resource at all but as some sort of monument to man's humanity to mammals. This lack of appreciation of economic factors is illustrated in chapter 6 where the justification for discussing the economics of the whaling industry solely on the basis of the Japanese industry and not that of the USSR is partly the fault of a deficiency of data but mainly results from the fact that the same economic arguments apply to both nations; and in any case slaughtered whales are not interested in "the nicety of distinction between state capital and private capital" (p46). Although the whales may not be bothered in the short run, to dismiss this vital distinction in the exploitation

Scientific Method (Popper's World 3)
Neural Modelling (Popper's World 2)
Genetic Modelling (Popper's World 1)

are operationally isomorphic processes for
the very survival of all Life on Earth.

Recent scientific and technical books

Mathematics

- ALLEN, Arnold O. Probability, Statistics, and Queuing Theory, With Computer Science Applications (Computer Science and Applied Mathematics, a Series of Monographs and Textbooks) Pp.xvi+390. ISBN-0-12-051050-2. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £29.50; £19.15.
- MURDOCH, J. Queuing Theory: Worked Examples and Problems. Pp.vi+88. ISBN-0-333-21702-0. (London and Basingstoke: The Macmillan Press, Ltd., 1978.) £2.95.
- WATERMAN, D. A., and HAYES-ROTH, Frederick (edited by). Pattern-Directed Inference Systems. Pp.xiv+638. ISBN-0-12-73750-3. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £33; £21.45.

Physics

- GRANZER, F., PARETZKE, H., and SCHOPPER, E. (edited by). Solid State Nuclear Track Detectors (Proceedings of the 9th International Conference, Neuberberg/München, 30th September-4th October 1976) Vol. 1. Pp.xcxi+1-736. Vol. 2. Pp.xvii+737-1350. ISBN-0-08021639-5. (Oxford and New York: Pergamon Press, 1978.) £80 the set.
- MARTIN, W. C., ZALUBAS, Romuald, and HAGAN, Lucy Atomic Energy Levels—The Rare-Earth Elements: The Spectra of Lanthanum, Cerium, Praseodymium, Neodymium, Promethium, Samarium, Europium, Gadolinium, Terbium, Dysprosium, Holmium, Erbium, Thulium, Ytterbium, and Lutetium (National Standards Reference Data System—National Bureau of Standards 60) Pp.vii+411. (Washington, DC: US Government Printing Office, 1978.) \$9.50.
- MEER, J. M., and CRAIGGS, J. D. (edited by). Electrical Breakdown of Gases. (Wiley Series in Plasma Physics) Pp.x+878. ISBN-0-471-99553-3. (Chichester and New York: Wiley-Interscience, John Wiley and Sons, 1978.) £35, \$75.
- ISENBERG, Cyril The Science of Soap Films and Soap Bubbles. Pp.xii+188. ISBN-0-905028-02-3. (Clevedon, Avon: Tetra, Ltd., 5 Elton Road, 1978.) £8.50, \$20. (Pub 10 Aug. '78.)
- ISHIMARU, Akira. Wave Propagation and Scattering in Random Media. Vol. 2 Multiple Scattering, Turbulence, Rough Surfaces, and Remote Sensing. Pp.xix+253-572. ISBN-0-12-374702-3 (v.2). (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich Publishers, 1978.) £26.50; £17.20.
- POATE, J. M., TU, K. N., and MAYER, J. W. Thin Films—Interdiffusion and Reactions (The Electrochemical Society Series) Pp.x+578. ISBN-0-471-02238-1. (New York and Chichester: Wiley-Interscience, John Wiley and Sons, 1978.) £25.
- ROBINSON, L. C. Physical Principles of Far-Infrared Radiation (Methods of Experimental Physics, Vol. 10) Pp.xi+460. ISBN-0-12-475910-6. (New York and London: Academic Press, 1973.) np.
- ROSE-INNES, A. C. and RHODERICK, E. H. Introduction to Super Conductivity. Second edition. (International Series in Solid State Physics, Vol. 6) Pp.xviii+237. ISBN-0-08-021652-8. (Oxford and New York: Pergamon Press, 1978.) Hard cover £15; Flexi cover £6.
- STREIT, L. (edited by). Many Degrees of Freedom in Field Theory (NATO Advanced Study Institutes Series B, Physics, Vol. 30) Pp.vii+248. ISBN-0-306-35730-5. (New York and London: Plenum Press, 1978. Published in co-operation with NATO Scientific Affairs Division.) \$33.

Chemistry

- BARRETT, Charles S., LEYDEN, Donald E., NEWKIRK, John B., and RUUD, Clayton O. (edited by). Advances in X-Ray Analysis, Vol. 21 (Proceedings of the Twenty-Sixth Annual Conference on Applications of X-Ray Analysis, held in Denver, August 3-5, 1977). Pp.xvi+325. ISBN-0-306-38421-3. (New York and London: Plenum Press, 1978.) £47.40.
- BEYNON, J. H. (prepared for publication by). Recommendations for Symbolism and Nomenclature for Mass Spectroscopy (International Union of Pure and Applied Chemistry Physical Chemistry Division Commission on Molecular Structure and Spectroscopy) Pp.65+73. ISBN-0-08-022368-0. (Oxford and New York: Pergamon Press, 1978.) £3.30.
- DAVIES, D. I., and PARROTT, M. J. Free Radicals in Organic Synthesis. (Reactivity and Structure Concepts in Organic Chemistry, Vol. 7) Pp.xii+169. ISBN-0-354-08723-0. (Berlin and New York: Springer-Verlag, 1978.) DM56; £28.
- DOLPHIN, David (edited by). The Porphyrins Vol. 2. Structure and Synthesis, Part B. Pp.xix+437. ISBN-0-12-220102-7. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$46.50, £33.
- DUNITZ, J. D., et al. (edited by). Structure and Bonding Vol. 34. Novel Aspects. Pp.iv+220. ISBN-0-354-08676-5. (Berlin and New York: Springer-Verlag, 1978.) DM74, \$37.
- GÜTLICH, Philipp, LINK, Rainer, and TRAUTWEIN, Alfred. Mossbauer Spectroscopy and Transition Metal Chemistry (Inorganic Chemistry Concepts, Vol. 3) Pp.x+280. ISBN-0-354-08671-4. (Berlin and New York: Springer-Verlag, 1978.) DM76; £38.
- NIKITIN, E. E., and ZULICKE, L. Selected Topics of the Theory of Chemical Elementary Processes (Lecture Notes in Chemistry, Vol. 8) Pp.ix+175. ISBN-0-354-08768-0. (Berlin and New York: Springer-Verlag, 1978.) DM20, \$10.
- WHIFFEN, D. H. (prepared for publication by). Expression of Results in Quantum Chemistry. (International Union of Pure and Applied Chemistry Physical Chemistry Division Commission on Physicochemical Symbols, Terminology and Units) Pp.75+79. ISBN-0-08-022367-2. (Oxford and New York: Pergamon Press, 1978.) £3.30.

Technology

- AUER, P. L., ARMSTRONG, Ellis L., et al. Unconventional Energy Resources Hydraulic Resources. (World Energy Resources 1985-2020, Renewable Energy Resources. The Full Reports to the Conservation Commission of the World Energy Conference.) Pp.x+181. ISBN-0-902852-98-1. (Guildford: IPC Science and Technology Press, 1978.) £12, \$31.20.
- BLOODWORTH, I. J., et al. World Energy Demand to 2020. (World Energy Resources 1985-2020, World Energy Demand. The Full Report to the Conservation Commission of the World Energy Conference.) Pp.x+109. ISBN-0-902852-99-X. (Guildford: IPC Science and Technology Press, 1978. Published for the WEC.) £12, \$31.20.
- CHEREMISINOFF, Nicholas P. Fundamentals of Wind Energy. Pp.v+170. ISBN-0-250-40255-6. (Ann Arbor, Mich.: Ann Arbor Science Publishers, Inc., 1978. Distributed in UK by John Wiley and Sons, Ltd., Chichester.) £6.90.
- DESPIRAIRES, Pierre, McCORMICK, W. T., FISH, L. W., KALISCH, R. B., and WANDER, T. J. Worldwide Petroleum Supply Limits: The Future for World Natural Gas Supply. (World Energy Resources 1985-2020, Oil and Gas Resources. The Full Reports of the Conservation Commission of the World Energy Conference.) Pp.x+227. ISBN-0-902852-95-7. (Guildford: IPC Science and Technology Press, 1978. Published for the WEC.) £12; \$31.20.
- FOSTER, J. B., et al. The Contribution of Nuclear Power to World Energy

Supply, 1975-2020. (World Energy Resources, 1985-2020, Nuclear Resources. The Full Report to the Conservation Commission of the World Energy Conference.) Pp.x+203. ISBN-0-902852-96-5. (Guildford: IPC Science and Technology Press, 1978. Published for the WEC.) £12, \$31.20.

PEDERSEN, Erik S. Nuclear Power Vol. 1 Nuclear Power Plant Design. Pp.xv+558. ISBN-0-250-40230-0. Vol. 2 Nuclear Power Project Management. Pp.xii+397. ISBN-0-250-40231-9. (Ann Arbor, Michigan: Ann Arbor Science Publishers, Inc., 1978.) £18.60 each volume.

PETERS, W., and SCHILLING, H.-D. With the assistance of PICKHARDT, W., WIEGAND, D., and HILDEBRANDT, R. An Appraisal of World Coal Resources and their Future Availability (World Energy Research Resources 1985-2020, Coal Resources. The Full Report of the Conservation Commission of the World Energy Conference.) Pp.x+139. ISBN-0-902852-97-3. (Guildford: IPC Science and Technology Press, 1978.) £12, \$31.20.

HALLING, J. (edited by). Principles of Tribology. Pp.xiv+401. ISBN-0-333-15496-7. (London and Basingstoke: The Macmillan Press, Ltd., 1978.) £6.95.

RINGWOOD, A. E. Safe Disposal of High Level Nuclear Reactor Wastes: a New Strategy. Pp.vi+63. ISBN-0-7081-1754-6. (Canberra: Australian National University Press, 1978. Distributed in the UK, Continent of Europe, Middle East and Africa by Eurospan, Ltd., 3 Henrietta Street, London WC2, North America by Books Australia, Norwalk, Conn.) £2.40.

SIMEONS, Charles. Energy Research and Development Programmes in Western Europe. Pp.xvii+323. ISBN-0-444-41711-7. (Amsterdam, Oxford and New York: Elsevier Scientific Publishing Company, 1978.) Dfl 100, \$43.50.

Applied biology

- ARBER, W. et al. (edited by). Current Topics in Microbiology and Immunology, Vol. 80. Pp.lv+170. ISBN-0-354-08781-8. (Berlin and New York: Springer-Verlag, 1978.) DM78, \$39.
- ARIENS, E. J., SIMONIS, A. M., and OFFERMEIER, J. Introduction to General Toxicology. Pp.vii+252. ISBN-0-12-060552-X. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976.) \$17.50, £11.35.
- BAAN, Jan, NOORDERGRAAF, Abraham, and RAINES, Jeff (edited by). Cardiovascular System Dynamics. Pp.xv+618. ISBN-0-262-18078-2. (Cambridge, Mass. and London: The MIT Press, 1978.) \$70.
- BAGENAL, Timothy (edited by). Methods for Assessment of Fish Production in Fresh Waters. Third Edition. (IBP Handbook No. 3) Pp.xv+365. ISBN-0-632-00125-9. (Oxford and London: Blackwell Scientific Publications, 1978. Distributed in the USA and Canada by J. B. Lippincott Company, Philadelphia and Toronto.) £8.50.
- BROWN, A. W. A. Ecology of Pesticides. Pp.vii+525. ISBN-0-471-10790-5. (New York and Chichester: Wiley-Interscience, John Wiley and Sons, 1978.) £17.65.
- CRANDALL, Barbara F., and BRAZIER, Mary A. B. (edited by). Prevention of Neural Tube Defects: The Role of Alpha-Fetoprotein (UCLA Forum in Medical Sciences, No. 20) Pp.xvi+264. ISBN-0-12-195350-5. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$16.50, £10.70.
- CUDKOWICZ, Gustave, LANDY, Maurice, and SHEARER, Gene M. (edited by). Natural Resistance Systems Against Foreign Cells, Tumors, and Microbes (Proceedings of an International Conference held at Timber Cove Inn, Jenner, California, October 18-22, 1976) Pp.xi+299. ISBN-0-12-199735-9. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$15, £9.75.
- DE SANTO, Robert S. Concepts of Applied Ecology (Heidelberg Science Library) Pp.ix+310. ISBN-0-354-90301-1. (Berlin and New York: Springer-Verlag, 1978.) DM28, \$14.
- EDWARDS, David J. Salmon and Trout Farming in Norway. Pp.xii+195. ISBN-0-85238-093-3. (Farnham, Surrey: Fishing News Books, Ltd., 1978.) £9.
- EPSTEIN, Murray (edited by). The Kidney in Liver Disease. Pp.xv+374. ISBN-0-444-00240-5. (New York, Oxford and Shannon: Elsevier North-Holland, Inc., 1978. Distributed outside USA and Canada by Thomson Books, P.O. Box 85, Limerick.) \$32.50.
- FELIX, H., HAEMMERLI, G., and STRAULI, P. Dynamic Morphology of Leukemia Cells: a Comparative Study by Scanning Electron Microscopy and Microcinematography. Pp.xi+191. ISBN-0-354-08495-9. (Berlin and New York: Springer-Verlag, 1978.) DM98, \$49.
- FICAT, R. Paul, and HUNGERFORD, David S. Disorders of the Patellofemoral Joint. Pp.xv+249. ISBN-0-225-48125-3. (Paris: Masson Toubridge Wells Abacus Press, Ltd., 1977.) £21.50.
- FRIESEN, Stanley R. (edited by). BOLINGER, Robert E. (editorial consultant). Surgical Endocrinology: Clinical Syndromes. Pp.xv+430. ISBN-0-397-50384-9. (Philadelphia and Toronto: J. B. Lippincott Company, 1978.) np.
- GINSBURG, Victor (edited by). Methods in Enzymology. Vol. 50: Complex Carbohydrates, Part C. Pp.xix+628. ISBN-0-12-181950-7 (v. 50). (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$48.50, £31.50.
- HARRISON, R. G. Clinical Embryology. (Monographs for Students of Medicine) Pp.vii+250. ISBN-0-12-327840-6. (London and New York: Academic Press, 1978.) £4.80, \$9.35.
- HENRY, John Bernard, and GIEGEL, Joseph L. Quality Control in Laboratory Medicine (Transactions of the First Inter-American Symposium, Key Biscayne, Florida, April 8-9, 1976) Pp.xii+237. ISBN-0-89352-008-X. (New York: Masson, Toubridge Wells Abacus Press, Ltd., 1977.) £21.75.
- HOLDGATE, M. W., and WOODMAN, M. J. (edited by). The Breakdown and Restoration of Ecosystems (NATO Conference Series, I: Ecology, Vol. 3) Pp.xi+496. ISBN-0-306-32803-8. (New York and London: Plenum Press, 1978. Published in coordination with NATO Scientific Affairs Division.) \$35.
- HOOD, J. D. (edited by). Vestibular Mechanisms in Health and Disease (VI Extraordinary Meeting of the Barany Society) Pp.xx+378. ISBN-0-12-354250-2. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £13.80.
- IARC MONOGRAPHS ON THE EVALUATION OF THE CARCINOGENIC RISK OF CHEMICALS TO HUMANS. Vol. 17. N-Nitroso Compounds. Pp.365. (Lyon: International Agency for Research in Cancer, 1978. Distributed by WHO, Geneva; HMSO, London.) Sw fr 525.
- KING, J. O. L. An Introduction to Animal Husbandry. Pp.vii+434. ISBN-0-632-00255-7. (Oxford and London: Blackwell Scientific Publications, New York: Halsted Press, a Division of John Wiley and Sons, Inc., 1978.) £9.80.
- KOEHLER, J. K. (edited by). Advances in Techniques in Biological Electron Microscopy II. Specific Ultrastructural Probes. Pp.x+244. ISBN-0-354-08503-3. (Berlin and New York: Springer-Verlag, 1978.) DM54, \$27.
- KOZLOWSKI, T. T. (edited by). Water Deficits and Plant Growth Vol. 5. Water and Plant Disease. Pp.xv+323. ISBN-0-12-424155-7 (v. 5). (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$31.50; £20.45.
- LAERUM, O. D., BIGNER, D. D., and RAJEWSKY, M. F. (edited by). Biology of Brain Tumors (A series of Workshops on the Biology of Human Cancer, Report No. 3. UICC Technical Report Series, Vol. 30) Pp.209. ISBN-92-9018-030-7. (Geneva: International Union Against Cancer, 3 rue du Conseil-Général, 1978.) Sw Fr 15.
- LI, P. H., and SAKAI, A. (edited by). Plant Cold Hardness and Freezing Stress: Mechanisms and Crop Implications (Proceedings of an International Plant Cold Hardness Seminar held in St. Paul, Minnesota, November 2-4, 1977) Pp.xii+416. ISBN-0-12-447650-3. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$21.50; £13.95.

MURPHY, Gerald P. (editor-in-chief). *International Advances in Surgical Oncology*, Vol. 1. Pp.xi+288. ISBN-0-8451-0500-0 (New York: Alan R. Liss, Inc., 1978.) np.

NATELSON, Samuel, and NATELSON, Ethan A. *Principles of Applied Clinical Chemistry: Chemical Background and Medical Applications*, Vol. 2: The Erythrocyte—Chemical Composition and Metabolism. Pp.xiv+560. ISBN-0-306-35232-X (v. 2). (New York and London: Plenum Press, 1978.) \$47.40.

PARISER, Ernst R., WALLERSTEIN, Mitchell B., CORKERY, Christopher J., and BROWN, Norman L. *Fish Protein Concentrate: Panacea for Protein Malnutrition*. (International Nutrition Policy Series.) Pp.xix+296. ISBN-0-262-16069-2 (Cambridge, Mass. and London: The MIT Press, 1978.) \$17.50.

PERLMAN, D. (edited by). *Advances in Applied Microbiology*, Vol. 23. Pp.x+300. ISBN-0-12-002623-6 (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$23. \$14.95.

PRECHT, Wolfgang. *Neuronal Operations in the Vestibular System* (Studies of Brain Function, Vol. 2). Pp.viii+226. ISBN-3-540-08549-1. (Berlin and New York: Springer-Verlag, 1978.) DM43; \$21.50.

PREUSSMANN, R., CASTEGNARO, M., WALKER, E. A., and WASSERMAN, A. E. (edited by). BOGAN, H. (editor-in-chief). DAVID, W. (technical editor for IARC). *Environmental Carcinogens: Selected Methods of Analysis*, Vol. 1: Analysis of Volatile Nitroamines in Food. (World Health Organization, International Agency for Research on Cancer.) (IARC Scientific Publications, No. 18.) Pp.xii+212. ISBN-92-832-1118-9. (Lyon: International Agency for Research on Cancer, 1978. Distributed by: WHO, Geneva; HMSO, London.) Sw.fr.90. \$45.

ROBERTS, Jay, ADELMAN, Richard C., and CRISTOFALO, Vincent J. (edited by). *Pharmacological Intervention in the Aging Process*. (Advances in Experimental Medicine and Biology, Vol. 97.) Pp.xii+335. ISBN-0-306-32697-3. (New York and London: Plenum Press, 1978.) \$35.40.

RODRICKS, Joseph V., HESSELTINE, Clifford W., and MEHLMAN, Myron A. (edited by). *Mycotoxins in Human and Animal Health*. (Proceedings of a Conference convened at University of Maryland University College, College Park, Maryland, October 4-8, 1976.) Pp.xvii+807. ISBN-0-930376-00-5. (Park Forest South, Ill.: Pathotex Publishers, Inc., 1977.) np.

SPENCER, D. M. (edited by). *The Powdery Mildews*. Pp.xix+565. ISBN-0-12-636850-2. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £28. \$54.75.

TROLLER, John A., and CHRISTIAN, J. H. B. *Water Activity and Food*. (Food Science and Technology: a Series of Monographs.) Pp.xiv+235. ISBN-0-12-700650-8. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$19.50; £12.65.

VAN DER REIJ, Leo (edited by). *The Esophagus*. (Frontiers of Gastrointestinal Research, Vol. 3.) Pp.x+166. ISBN-3-8055-2700-4. (Basel, London and New York: S. Karger, 1978.) SF/DM98; \$49.

WALKER, E. A., CASTEGNARO, M., GRICUTE, L., and LYLE, R. E. (edited by). DAVIS, W. (technical editor for IARC). *Environmental Aspects of N-Nitroso Compounds*. (Proceedings of a Working Conference held at the New England Center for Continuing Education, University of New Hampshire, Durham, New Hampshire, USA, 22-24 August, 1977.) (World Health Organization, International Agency for Research on Cancer, IARC Scientific Publications, No. 19.) Pp.xiv+566. ISBN-92-832-1119-7. (Lyon: International Agency for Research on Cancer, 1978. Distributed by: WHO, Geneva; HMSO, London.) Sw.fr.100.

WARD, David C., and TAITER, Peter (edited by). *Replication of Mammalian Parvoviruses*. Pp.x+547. ISBN-0-87969-120-4. (Cold Spring Harbor: Cold Spring Harbor Laboratory, 1978.) \$45.

WEBER, George (edited by). WEBER, Catherine E. Forrest (technical editor). *Advances in Enzyme Regulation*, Vol. 16. (Proceedings of the Sixteenth Symposium on Regulation of Enzyme Activity and Synthesis in Normal and Neoplastic Tissues, held at Indiana University School of Medicine, Indianapolis, Indiana, October 3 and 4, 1977.) Pp.xiv+485. ISBN-0-06-022646-9 (Oxford and New York: Pergamon Press, 1978.) £40.

WEINSTEIN, Louis, and FIELDS, Bernard N. (edited by). *Seminars in Infectious Diseases*, Vol. 1. Pp.vii+301. ISBN-0-913258-54-7. (New York: Stratton, Intercontinental Medical Book Corporation, 1978.) \$35.

WHITE, Dennis, and LYONS, E. A. (edited by). *Ultrasound in Medicine*, Vol. 4. (Proceedings of the 22nd Annual Meeting of the American Institute of Ultrasound in Medicine, in conjunction with the 6th Annual Meeting of the American Society of Ultrasound Technical Specialists.) Pp.xiv+668. ISBN-0-306-34205-7. (New York and London: Plenum Press, 1978.) \$71.40.

WILLIAMSON, G., and PAYNE, W. J. A. *An Introduction to Animal Husbandry in the Tropics*. (Tropical Agriculture Series.) Third edition. Pp.x+755. ISBN-0-582-46813-2. (London and New York: Longman, 1978.) £10.95.

WOLF, Paul L. *Interpretation of Biochemical Multitest Profiles: An Analysis of 100 Important Conditions*. Pp.296. ISBN-0-89352-002-0. (New York: Masson; Tunbridge Wells: Abacus Press, Ltd., 1977.) £16.65.

Psychology

BUNDY, A., BURSTALL, R. M., WEIR, S., and YOUNG, R. M. *Artificial Intelligence: an Introductory Course*. Pp.viii+253. ISBN-0-85224-340-5. (Edinburgh: Edinburgh University Press, 1978.) £5.

CANAVAN-GUMP, Donah, GARNER, Katherine, and GUMP, Peter. With contributions by COHEN, Nina E., and PAPPO, Maurice. *The Successful Learning Personality: Theory and Research with Implications for the Social Psychology of Achievement*. Pp.xiv+256. ISBN-0-669-01075-8. (Lexington, Mass. and Farnborough, Hants.: Lexington Books, 1978.) £13.

ELLIS, Norman R. (edited by). *International Review of Research in Mental Retardation*, Vol. 9. Pp.xiv+301. ISBN-0-12-366209-5. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$23; £14.95.

GOTTLIEB, Gilbert (edited by). *Studies on the Development of Behavior and the Nervous System*, Vol. 4: Early Influences. Pp.xvii+358. ISBN-0-12-609304-0. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$22.50; £14.60.

HALL, Morris, BRESNAN, Joan, and MILLER, George A. (edited by). *Linguistic Theory and Psychological Reality*. (MIT Bicentennial Series.) Pp.xv+329. ISBN-0-262-08095-8. (Cambridge, Mass. and London: The MIT Press, 1978.) \$17.50.

KAVANAGH, James P., and STRANGE, Winifred (edited by). *Speech and Language in the Laboratory, School, and Clinic*. Pp.xvii+511. ISBN-0-262-11065-2. (Cambridge, Mass. and London: The MIT Press, 1978.) £22.50.

LOMAX, Elizabeth M. R. In collaboration with KAGAN, Jerome and ROSENKRANTZ, Barbara G. *Science and Patterns of Child Care*. (A Series of Books in Psychology.) Pp.xv+247. ISBN-0-7167-0296-7. (San Francisco: W. H. Freeman and Company, 1978.) Cloth \$12, Paper \$6.

NOBLE, William G. *Assessment of Impaired Hearing: a Critique and a New Method*. Pp.xiv+348. ISBN-0-12-520050-1. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$21. £13.65.

RANDHAWA, Bikkar S., and COFFMAN, William E. (edited by). *Visual Learning, Thinking, and Communication*. (Academic Press Series in Cognition and Perception.) Pp.xiv+227. ISBN-0-12-579450-9. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$18; £11.70.

REISE, Hayne W., and LIPSITT, Lewis P. (edited by). *Advances in Child Development and Behavior*, Vol. 12. Pp.xiv+317. ISBN-0-12-009712-5. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$22; £14.30.

ROSENBLATT, Jay S., HINDE, Robert, BEER, Colin, and BUSNEL, Marie-Claire. *Advances in the Study of Behavior*, Vol. 8. Pp.xiv+261. ISBN-0-12-004506-7. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$19.50; £12.65.

SCHWAB, John J., and SCHWAB, Mary E. *Sociocultural Roots of Mental Illness: An Epidemiologic Survey*. (Topics in General Psychiatry.) Pp.xii+338. ISBN-0-306-31089-9. (New York and London: Plenum Medical Book Company, 1978.) \$33.

obituary

D. R. Chick

PROFESSOR D. R. CHICK, F.I.E.E., F.Inst.P., F.I.E.R.E., Head of the Department of Electronic and Electrical Engineering at the University of Surrey since 1965, died suddenly at his home in Surrey on 11 June 1978 aged 61.

He was one of the many young scientists in the 1930s who began their working life on the applications of radar, which were so vital to the winning of the war. His experiences in the field in wartime conditions, where it was so essential to impress the young local commanders that the civil scientists were not wasting everybody's time, surely helped him form some of his strongest characteristics: a quick and accurate assessment of people, straight, often blunt speaking, a sound scientific and economic judgment, and not least a strong personal loyalty to his own staff and colleagues. One such experience where the accommodation offered to him and his co-workers fell far below that expected considering their equivalent army rank led to a walk-out, much to the distress of the commanding officer, who to save his own reputation swallowed his pride and begged their return.

Immediately after the war, Chick turned to industrial research, joining the A E I company at the new research laboratory of Aldermaston Court. For 17 years, he was in charge of various nuclear physics activities of the company and made large contributions in several different ways. His group developed and constructed electrostatic generators and a helical particle accelerator for basic physics research, and among much fundamental work he and colleagues measured excited levels in arsenic 75 produced by radiative capture of protons by germanium 74. This led to a patent application in 1957 relating to the production of p-n junctions in germanium or silicon by nuclear transmutation following irradiation with protons. It is significant that today transmutation doping of silicon by neutrons is used for special devices.

Also, with Sir George Thomson, a large section was devoted to the thermonuclear research programme, so important in future fusion reactors, using a torus named Sceptre. In 1957, this group, working closely with a Harwell team possessing a larger torus

named Zeta, announced the production of neutrons from the discharge and subsequently studied some of the instabilities which develop in toroidal gas discharges carrying large currents.

His third major achievement in this period was the installation of a 5 MW pool type research reactor designed and developed by his group in conjunction with A E I John Thompson Ltd. This reactor was the first publicly owned one and received reactor licence no. 1 in the U.K.; it was officially opened by H.R.H. the Duke of Edinburgh in 1959. It was used for research and contract work and two similar reactors were sold by A E I John Thompson, one in Germany and one to the Atomic Energy Authority at Aldermaston.

In the mid-60s, it was appropriate that this wealth of experience in both the civil service and industry should be passed to one of the new universities which resulted from the publication of the Robbins report. When Professor Chick joined the then Battersea College of Advanced Technology as Head of the Department of Electrical and Control Engineering, he had a decided policy that his department would become known for both its research and industrial liaison as well as for its academic achievements.

He grouped his research effort into a few main projects, and his forward thinking is demonstrated by the fact that in 1966 he formed a team to work on ion implantation, then a speculative research area, now a major part of microelectronics technology, and he saw this group grow and become recognised as one of the major ones in the U.K. with a good reputation abroad.

He also formed an industrial electronics group which made the expertise of his academic staff available to industry on a contract research basis, and already the turnover from this venture has exceeded the £1 million mark. These successes, together with the establishment of a compulsory industrial year for undergraduates, M.Sc. projects sponsored by many firms, several collaborative Ph.D. programmes and industrially supported research fellowships, are a continuing demonstration of his concept of what makes a good academic engineering department in present day conditions—that is, one where its staff are not only scholars but also professional engineers aware of the needs of the industrial world and

of where real wealth is created.

Professor Chick will be sadly missed by his colleagues and friends for his considerable intellectual qualities, his dry humour and his loyalty. Only days before his death, he visited a sick colleague in hospital carrying ice and a radio. The radio was returned as not working, and when told that the reason was that the batteries were in the wrong way round, he beamed and laughingly said, 'Failed the first term's examination!'

K. G. Stephens
T. E. Allibone

Moses Kunitz

THE death of Moses Kunitz on 24 April 1978 at the age of 90 brought to a close the story-book career of a young émigré from the Russian revolution who was to become a leading scientist in the field of protein research.

Kunitz arrived in New York early in the second decade of this century and found employment in the laboratory of Jaques Loeb, the famous experimental cell physiologist at the then Rockefeller Institute. Dr Loeb recognized the value of Kunitz's quick but careful work and encouraged him to pursue his education in the evenings, first at Cooper Union and then at Columbia University where he received his Ph.D. degree in 1923.

When John H. Northrop was appointed to the place left vacant by Dr Loeb's death, he invited Kunitz to remain and continue his study of proteins. This happy, fruitful union lasted until Dr Northrop left for California in 1951.

Kunitz was an acute observer and experimentalist. He learned to know the properties of proteins so well that he could estimate with some accuracy the likelihood of a protein crystallizing just by watching a flocculation during salt or acid precipitation. One example of this ability stands out in my mind. After attempts by other workers to crystallize the toxic protein ricin during World War II had failed, Kunitz was asked to have a try at it. I brought the package of partially purified ricin to him late one afternoon and remained to watch him weigh a quantity of it, dissolve it in dilute buffer, and distribute aliquots into a number of tubes. He then added increasing numbers of tiny drops of acid to the various tubes. As a cloudiness developed

in a few tubes prior to flocculation, he examined them carefully against indirect light, murmuring to himself 'it isn't so bad', and put the tubes in the refrigerator. The next morning crystals of the ricin protein were clearly visible in two of the tubes.

Kunitz's isolation of some 18 enzymes and precursors in crystalline form from animal and plant tissues and yeast, each with evidence of its purity went far to confirm Northrop's thesis that enzymes are proteins.

Although his name is associated primarily with protein crystallization, Kunitz's contributions and capacity were much broader. In one of his least known and yet more important papers, 'The Kinetics and Thermodynamics of Reversible Denaturation of Crystalline Soybean Trypsin Inhibitor' (*J. gen. Physiol.* 1948, 32, 241), Kunitz demonstrated by enzymatic and physico-chemical methods that renaturation of the inhibitor yielded a product indistinguishable from the original protein. Using a kinetic approach to the equilibrium reaction from both sides at different temperatures, he obtained clean thermodynamic values for each process. This study laid to rest the prevailing notion that so complicated a process as protein denaturation could not be completely reversible.

On the occasion of Kunitz's being awarded the Carl Neuberg Medal in 1957 by the American Society of European Chemists and Pharmacists, Dr Northrop wrote the following: 'Dr Kunitz possesses to a rare degree the abilities of a research worker of the first rank in his chosen field—imagination, ingenuity, and persistence, great technical skill, mathematical facility and thorough theoretical knowledge. It is not surprising, therefore, that he has been able to solve almost every problem he has attempted. Some of them are of great importance. The isolation and crystallization of ribonuclease, hexokinase, and desoxyribonuclease placed the protein nature of enzymes in general on firm experimental foundation. In addition, the nucleases have been invaluable tools in the elucidation of the chemistry of the nucleic acids, those remarkable substances that appear to be the very "stuff of life".'

Kunitz was the first to demonstrate that certain enzymes, especially the proteases of mammals, existed in glandular tissues in an inactive form. This formation explained why the tissue proteins were not digested. He went on to study the autocatalytic or catalytic conversion of these precursors to active enzymes following secretion into the digestive fluids.

To present-day biomedical investigators Kunitz may be remembered for having purified the pancreatic nucleases, ribonuclease and deoxyribonuclease which, as Dr Northrop has noted, have become and will continue to be very important in identifying the functions of the various nucleic acids.

During his lifetime, Dr Kunitz received a number of honours including the Carl Neuberg Medal and membership in the National Academy of Sciences. He was made a full member of the Rockefeller Institute in 1950 and became a Professor when the Institute became a University.

Moses Kunitz is survived by a son, Jaques, and a daughter, Rosaline Albert.

Roger M. Herriott

R. K. Murton

RON MURTON was one of the few really professional scientific ornithologists, who combined careful and patient field observation of birds with rigorous scientific investigation on their anatomy and physiology. His death from a heart attack on 12 June 1978, at the early age of 46, came as a great shock to his colleagues and friends. Although he had a previous attack some weeks earlier, and had been seriously ill, he had returned to part-time work with his enthusiasm undiminished, and he appeared to be making a good recovery. Up till this spring, he had always had such energy and drive, and the ability to work at high pressure sparing neither himself nor his colleagues, that we had never imagined that he would ever suffer from ill health.

Ronald Keir Murton was born in 1932. The first sixteen years of his working life, after graduating in Zoology at University College London, were with the Infestation Control Division of the Ministry of Agriculture, Fisheries and Food. He became immediately involved in the study of birds which are agricultural pests, and with the wood pigeon in particular. The damage done by wood pigeons to brussels sprouts and other brassicae, amounting to many millions of pounds every year, was well known, and the main attempt at control was by supplying cheap cartridges to enable farmers and others to shoot the birds. This gave much pleasure to these sportsmen, but, as Murton soon showed, it had little significant effect on pigeon numbers and it did not prevent the birds from doing economic damage. As a result of his findings the cheap cartridge scheme was stopped, saving the taxpayer a considerable sum of money, farmers whose sport became more expensive were less enthusiastic.

Murton's work on pigeons had a very practical aim, and it was successful in identifying the problems even if it was not possible to find any easy solution. Although the study was what would today be called 'customer orientated', it was also (as such studies may be) work of real scientific quality. His observations on pigeon behaviour

and reproductive physiology have seldom been equalled. The results are recorded in some 30 scientific papers, in a 'New Naturalist' monograph volume, and they formed the subject of the Barnes Memorial Lecture, which he was invited to give to the Association of Applied Biologists at the unusually early age of 32.

Although Dr Murton's career was almost entirely in research, he was closely associated with the academic world. In 1968–69 he enjoyed a year's sabbatical leave as a visiting lecturer at the University of Hong Kong. In 1974 he was appointed an Honorary Reader in the department of zoology at Hull University, and recently he was promoted to Honorary Professor. He was in demand to lecture to university students and others.

After leaving Hong Kong he returned briefly to the Ministry of Agriculture in 1969, and then transferred to Monks Wood Experimental Station, at that time under the Nature Conservancy. When the research branch of the Conservancy was reorganised as the Institute of Terrestrial Ecology he remained at Monks Wood, and was soon appointed as Head of the Sub-Division of Animal Function.

During the years when he was working on pigeons, which included important observations on feral pigeons in cities, Murton realised the importance of studies of the physiological changes in these birds as a basis for understanding their behaviour and their whole ecology. He became much involved in such topics as the photo-periodic control of the breeding cycle, and other, mainly laboratory, studies. He considered that these were the logical development of his earlier work. Many colleagues regretted his virtual abandonment of those field studies at which he had been so adept, and thought him ill advised to attach so much importance to his newer investigations. Not all his recent work has had the general approval given to his outstanding pigeon studies. Only time would have shown whether his switch in interest was, as he insisted, wise.

As well as observing birds in the field, Murton was one of the most outstanding bird photographers. As long ago as 1963 he was elected to Association of the Royal Photographic Society. During his comparatively short period, just twelve months, in Hong Kong, he made a surprisingly large collection of slides of the nesting habits of many of the rarer and more interesting species, several of which had not been previously photographed. He used his own photographs to illustrate his books and his lectures.

Kenneth Mellanby

announcements

Awards

The Fields Medal has been awarded to **Dr Daniel G. Quillen**, (Massachusetts Institute of Technology) for his work on algebraic K-theory.

The first recipient of the C D Nelson Award of the Canadian Society of Plant Physiologists, is **Dr J. Derek Bewley** (University of Calgary) for his research contributions to plant physiology.

The winners of the Filtration Society's 1978 Travel and Study awards are **G. H. Read** (Imperial College, London) and **Maureen Farrell** (Georgia). **Professor Frank Tiller** (University of Texas) has won the Society's gold medal for his work on delayed cake filtration.

Henry F. Schaeffer III (University of California, Berkeley) is the 1979 recipient of the ACS Award in Pure Chemistry.

Professor G. Vassart (University of Brussels) has been awarded the bi-annual 'Sir Charles Harrington Prize' by the European Thyroid Association for his work on the thyroglobulin messenger RNA.

The RIC have awarded the 1977 Meldola Medal and Prize to **Professor Eric Oldfield** (University of Illinois) for his work on the NMR spectroscopy of biochemical systems.

The Marlow Medal is restricted to Fellows of the Faraday Division of the Chemical Society of not less than 3yr standing on the closing date for application (1 January 1979). Applicants should be under 33 at this date. The award is based on publications on any subject normally published in JCS Faraday Transactions I and II. Applications to: Mrs Y. A. Fish, Faraday Division, The Chemical Society, Burlington House, London W1, UK.

Appointments

Professor Barbara E. Clayton to the Chair of Chemical Pathology and Human Metabolism at the University of Southampton.

Professor James R. Gray to Dean of the Faculty of Science at Heriot-Watt University.

Dr Asa G. H. Blakeley to the Chair of applied physiology at the University of Leicester.

Professor Peter G. Sammes to the Chair of Organic Chemistry at Leeds University.

Charles E. M. Yates to be Professor of Mathematical Logic at The University of Manchester.

Geoffrey Edwards to be chairman of the Thames Water Authority.

Dr Michael I. Gurr to head of the NIRD's Nutrition Department.

Meetings

25-30 November, **4th World Ozone Congress**, Houston (Dr A. Netzer, Environmental Sciences, University of Texas at Dallas, Richardson Texas 75080).

27 November-1 December, **Radiation Protection in Nuclear Power Plants and the Fuel Cycle**, Bristol (BNES, 1-7 Great George St, Westminster, London SW1, UK).

27-30 November, **Forage Conservation in the '80's**, Brighton (The Secretary, The British Grassland Society, Grassland Research Institute, Hurley, Maidenhead, Berks, UK).

28-30 November, **International Conference Antennas and Propagation**, London (The Institution of Electrical Engineers, Savoy Place, London WC2, UK).

30 November-1 December, **Cell Surfaces and Neoplasia**, London (Dr M. Moore, Paterson Laboratories, Christie Hospital & Holt Radium Institute, Manchester, UK).

30 November-1 December, **Symposium on Nutrition and Gastroenterology**, New York (Institute of Human Nutrition, Columbia University, College of Physicians and Surgeons, 701 West 168th St, New York, New York 10032).

1-2 December, **Current Concepts of Pain and its Treatment**, New York (Dr R. Duvoisin, ARNMD, Annesberg Building, Suite 14-02, 100th St at 5th Ave, New York, New York 10029).

2-3 December, **Science and Art in the 14th Century**, New York (Ann Collins,

The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021).

4-6 December, **3rd Annual Toxic Substances Control Conference**, Washington (Government Institutes Inc., 4733 Bethesda Ave, Washington, D.C. 20014).

6-7 December, **Engineering and the Environment: Harmony or Conflict?**, London (The Secretary, The Institution of Water Engineers and Scientists, 6-8 Sackville St, Piccadilly, London W1, UK).

7 December, **Structure Analysis for Surfaces**, York (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

11-14 December, **Design of Hydrologic Data Networks**, Tuscon (Meetings AGU, 1909 K St, Washington, D.C. 20006).

13 December, **Microstructural Instability: its Influence on long service life**, Birmingham (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).

14-19 December, **9th Texas Symposium on Relativistic Astrophysics**, Munich (Prof. J. Ehlers, MPI, Fohringer Ring 6, D 8000 Munchen 40, FRG).

18-19 December, **Pulsed NMR in Solids**, London (Prof J A S Smith, Chemistry Dept, Queen Elizabeth College, Campden Hill Rd, London W8, UK).

19-21 December, **Enzyme Active Sites**, London (Dr H. C. Watson, Dept of Biochemistry, University of Bristol Medical School, Bristol, UK).

3-5 January 1979, **16th Annual Solid State Physics Conference**, Warwick (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

4-5 January, **Laser Plasma Interactions**, Bangor (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

8-12 January, **11th Miami Winter Symposium**, Miami (UMED-PO Box 520875, Miami, Florida 33152).

14-16 January, **5th Annual Meeting of the International Embryo Transfer Society**, Denver (Mrs S Seidel, IETS, 3101 Arrowhead Road, LaPorte, Colorado 80535).

15-18 January, **2nd International Colloquium on Mars**, Pasadena (Dr C. W. Snyder, Jet Propulsion Laboratory, California Institute of Technology, 4800 Oak Grove Drive, Pasadena, California 91103).

22-23 January, **Medical and Industrial Applications of DNA**, Chicago (Robert S First Inc., 405 Lexington Ave, New York, New York 10017).

5-9 February, **International Conference on Neurotoxins**, South Australia (Dr I. W. Chubb, Dept of Human Physiology, Flinders Medical Centre, Bedford Park, South Australia 5042, Australia).

12-13 February, **Medical and Industrial Application of DNA**, London (Robert S. First Inc., 405 Lexington Ave, New York, New York 10017).

12-24 February, **World Climate Conference**, Geneva (WMO, Ave Giuseppe Motta 41, Geneva, Switzerland).

13-15 February, **Use of the Microprocessor as a Component in Measurement and Control Equipment**, Stevenage (Carole Meads, Sira Institute, South Hill, Chislehurst, Kent, UK).

21-24 February, **Hypoxia**, Banff (Arctic Institute of North America, University Library Tower, 2920-24th Ave N.W., Calgary, Alberta, Canada T2N1N4).

5-9 March, **30th Annual Conference on Analytical Chemistry and Applied Spectroscopy**, Cleveland (Mrs L. Briggs, 437 Donald Rd, Pittsburgh, Pasadena 15235).

12-14 March, **Controlled Environments Working Conference**, Madison (T. W. Tibbitts, Dept of Agriculture, University of Wisconsin-Madison, 1575 Linden Drive, Madison, Wisconsin 53706).

12-15 March, **International Cashew Symposium**, Cochin (Central Plantation Crops Research Institute, Kasaragod 670 124, Cannanore District, Kerala, India).

12-16 March, **Tunnelling '79**, London (The Secretary, Institution of Mining and Metallurgy, 44 Portland Place, London W1, UK).

14-16 March, **Thermal Characteristics of Tumors: Applications in Detection and Treatment**, New York (Conference Dept, The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021).

14-23 March, **Einstein Centenary in Jerusalem** (Israel Academy of Sciences and Humanities, PO Box 4040, Jerusalem, Israel).

26-29 March, **2nd European Conference on Surface Science**, Cambridge (Dr P. M. Williams, c/o VG Scientific Ltd, The Birches Industrial Estate, East Grinstead, Sussex, UK).

27 March-6 April, **7th Edmond de Rothschild School in Molecular Biophysics on the Structure of Chromatin**, Rehovot (Dr H. Eisenberg, Weizmann Institute of Science, Rehovot, Israel).

29-30 March, **International Conferences on Spectroscopy**, Miami (Vijay Mohan Bhatnagar, Alena Enterprises of Canada, PO Box 1779, Cornwall, Ontario, Canada K6H 5V7).

1-8 April, **International Ophiolite Symposium**, Nicosia (Chairman, Geological Survey Department, Nicosia, Cyprus).

2-4 April, **Vacuum Processes in the Electronics Industry**, Brighton (Carole Meads, Sira Institute, South Hill, Chislehurst, Kent, UK).

4-6 April, **International Conferences on the History of Museums and Collections in Natural History**, London (Mrs J. A. Diment, Palaeontology Library, British Museum (Natural History), Cromwell Road, London SW7, UK).

3-5 April, **Molecular Dynamics of Polymeric Systems**, Cambridge (Dr C. W. Smith, Secretary Dielectrics Society, Dept of Electrical Engineering, University of Salford, Salford, UK).

9-11 April, **Kinetics of State, Selected Species**, Birmingham (Mrs Y. A. Fish, Faraday Division, The Chemical Society, Burlington House, London W1, UK).

9-12 April, **11th National Atomic and Molecular Physics Conference**, Liverpool (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

17-20 April, **Electrostatics 1979**, Oxford (Dr J. F. Hughes, Dept of Electrical Engineering, University of Southampton, Southampton, UK).

24-25 April, **Advances in Optical Production Technology**, Teddington (Sira Institute Ltd, South Hill, Chislehurst, Kent, UK).

29 April-2 May, **Protein-nucleic acid Interactions**, Sitges (Prof. J. A. Subirana, Departamento de Quimica Macromolecular del C.S.I.C. Escuela T.S. de Ingenieros Industriales, Barcelona (28), Spain).

30 April-2 May, **Learning to use our Environment**, Seattle (Dr A. Roffman, Energy Impact Associates Inc, PO Box 1899, Pittsburgh, Pasadena 15230).

30 April-3 May, **International Conference on Malaria and Babesiosis**, Mexico (Dr J. P. Kreier, College of Biological Science, The Ohio State University, Columbus, Ohio 43210).

2-3 May, **Monitoring Toxic and Flammable Cases and Vapours**, London (Mrs R. Keiler, Sira Institute, South Hill, Chislehurst, Kent, UK).

19-20 April, **2nd Canadian Chromatography Conference**, Toronto (Alena Enterprises of Canada, PO Box 1779, Cornwall, Ontario, Canada K6H 5V7).

3-4 May, **6th International Symposium on Flammability and Fire Retardants**, Nashville (Alena Enterprises of Canada, PO Box 1779, Cornwall, Ontario, Canada K6H 5V7).

7-11 May, **1st International Colloquium on Receptors, Neurotransmitters and Peptide Hormones**, Capri (F. Fraiolo, Patologia Medica II, Policlinico Umberto I, Università, 00161 Rome, Italy).

15-18 May, **The Agricultural Industry and its effects on Water Quality**, Hamilton (Dr C. J. Schouten, Water and Soil Division, Ministry of Works and Development, Private Bag, Hamilton, New Zealand).

21-23 May, **Television Measurement**, London (Conference Secretariat, IERE, 99 Gower St, London WC1, UK).

21-23 May, **10th International Symposium on Chromatography and Electrophoresis**, Rimini (Dr Alberto Frigerio, Istituto di Ricerche Farmacologiche, Via Eritrea, 62-20157 Milan, Italy).

21-25 May, **Colloids and Surfaces**, Pittsburgh (Mrs G. Cohen, Carnegie Institute of Technology, Carnegie-Mellon University, Schenley Park, Pittsburgh, Pennsylvania 15213).

27 May-1 June, **14th World Gas Conference**, Toronto (Public Affairs Committee, 111 St Clair Ave West, Toronto, Ontario, Canada).

APPOINTMENTS VACANT

LASER SCIENTIST

RUTHERFORD LABORATORY

South Oxon

The Rutherford Laboratory is one of the Science Research Council's principal establishments for advanced work on the frontiers of physics, and one of Europe's leading centres for laser research.

We now have a vacancy for a plasma physicist in the Central Laser Facility to carry out numerical simulations of laser plasma interactions and laser produced compression of matter and to help to interpret experimental results in the light of the numerical predictions. The work involves the development and use of large computer codes (written in FORTRAN) on the dual IBM 360/195 at the Rutherford Laboratory and requires close co-operation with university groups using the Central Laser Facility. Preference will be given to applicants who have a basic knowledge of plasma physics, experience in atomic physics and/or numerical techniques in computational physics.

The appointment would be to the Higher Scientific Officer grade, within the salary range £4388 — £5829 — depending on age and experience.

Working conditions are excellent and benefits include generous holidays, sick leave allowance and contributory superannuation scheme.

Write or telephone for application form to:-
Ruth Jeans of the Personnel Group (Ext. 510)
quoting our reference No. VN 736

Closing date for applications 13 October 1978

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY SENIOR RESEARCH ASSISTANT

Applications are invited for a DOE financed post of Senior Research Assistant to study the behaviour of metallic pollutants in reclaimed derelict land within urban areas. Applicants should have research experience, and be interested in soil/plant relationships in difficult environments and the chemistry and biology of heavy metal pollution of terrestrial ecosystems.

The project is financed for three years from October 1, 1978. The initial salary will be £3,883 per annum.

Applications, together with the names of two referees, should be received not later than October 6 1978, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/933/N. 7219(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES Applications are invited for a LECTURESHIP IN PLANT PHYSIOLOGY

in which preference will be given to candidates with an interest in cellular or molecular aspects of the regulation of plant growth and development. The appointment will be effective from January 1, 1979, or as soon as possible thereafter.

Further details and forms of application, returnable not later than October 9, 1978, from the Staff Appointments Office, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. 634. 7229(A)

CORNELL ASSISTANT PROFESSORSHIP IN RADIO ASTRONOMY

A tenure-track position is available in experimental or theoretical radio astronomy or in radar astronomy with the Department of Astronomy at Cornell University. The appointee is expected to teach one course per semester and may be associated with the National Astronomy and Ionosphere Center (N.A.I.C.). Salary will be commensurate with experience and qualifications. The position may begin in July 1979 or with the fall semester of that year (starting August 24). Applicants should send resume and have three letters of recommendation sent to Professor K. I. Grisen, Chairman Department of Astronomy, Cornell University, Ithaca, N.Y. 14853.

Cornell University is an affirmative action equal-opportunity employer. 7264(A)

UNIVERSITY OF
ABERDEEN
POSTGRADUATE
RESEARCH ASSISTANT
IN BIOCHEMISTRY

This post is financed by the Cancer Research Campaign and is available from October 1978 for up to three years. The successful applicant will work on a project to investigate the nature, function and covalent modification of repetitive nucleotide sequences in eukaryotic DNA.

Salary on Range 1B scale for research and analogous staff £3,384 to £4,882 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen AB9 1FX, with whom applications (two copies) should be lodged by October 20, 1978. 7250(A)

THE CHINESE UNIVERSITY
OF HONG KONG
FACULTY OF MEDICINE

Applications are invited for the following foundation chairs:

ANATOMY
PHYSIOLOGY
PHARMACOLOGY

tenable at this new medical school with an annual student intake of 100. There will be opportunities for original research but considerable undergraduate teaching experience is essential. Non-medically qualified candidates may apply but preference will be given to those medically qualified. Successful applicants are expected to be in post latest end of 1980 or early 1981, to take part in compiling the basic medical sciences curriculum and installing departmental facilities. Teaching will begin in the fall term of 1981. The minimum salary for Professors will be HK\$11,735 per month (£1=HK\$9.2). Terms of service also include long leave, superannuation benefits (University 15%, appointee 5%), housing accommodation on campus and air passages. Full particulars of the appointment, together with copies of relevant documents concerning the medical school and the University, may be obtained from the Secretariat, The Chinese University of Hong Kong Shatin, New Territories, Hong Kong, to which applications (6 copies) giving full details of qualifications and experience and the names and addresses of 3 persons to whom reference may be made should be sent not later than December 15, 1978. 7251(A)

TROPICAL ECOLOGIST
(PLANT-INSECT INTERACTIONS)
The SMITHSONIAN TROPICAL
RESEARCH INSTITUTE announces
the availability of a 3-year appointment
for an ecologist.

The candidate will design and conduct investigations into the ecology of plants and animals of the Isthmus of Panama in order to assess the impact of the expected colonisation of this area by the Africanised Brazilian Honey Bees.

Interested candidates should submit a curriculum vitae, reprints of relevant publications, the names of references we may contact and a statement of the research that he/she is interested in pursuing in this area to the Director, S.T.R.I., Box 2072, Balboa, Canal Zone.

S.T.R.I. operates a variety of facilities on the Isthmus of Panama, including a Tropical Biology Library receiving 450 journals in Ecology, Animal Behavior and Evolution.

Salary \$17,638 to \$20,862 plus relocation expenses.

The Smithsonian Institution is an Equal Opportunity Employer.

Deadline for applications is December 31, 1978. 7252(A)

CSIRO

AUSTRALIA

Numerical Analyst

Division of Mathematics and Statistics

Canberra, Act

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees—2400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

General:

The Organization's Division of Mathematics and Statistics has approximately 108 staff, of whom 70% are professional scientists, located at centres and laboratories in all capital cities and some major country towns.

The Division's research in mathematics and statistics includes various aspects of fluid mechanics, statistical mechanics, optimization, computational mathematics, distribution theory, multivariate analysis, stochastic processes, geostatistics, statistical inference and experimental design. Application of this research to agricultural, biological, environmental, physical and industrial investigation currently includes the design and analysis of experiments and the modelling of ecological, physical, agricultural and climatological systems. Research is also being extended into industrial processes and mineral surveys.

Professional Scientists of the Division advise on the mathematical modelling and statistical analysis of investigations undertaken by other Divisions of CSIRO. The Division now wishes to appoint, to its small group working on numerical analysis, an experienced scientist at the Principal Research Scientist—Senior Principal Research Scientist level.

Duties:

To develop techniques in numerical analysis and advise scientists in other CSIRO Divisions on appropriate computational methods. The appointee would be expected to have a strong mathematical background, in areas of numerical analysis such as non-linear equations, computational complexity, optimization, special functions, and differential and integral equations.

Qualifications:

A Ph.D. degree or equivalent qualification, with extensive research experience in the relevant field.

Salary:

Principal Research Scientist—Senior Principal Research Scientist. \$A22,363-\$A29,366 p.a. Less experienced scientists may apply, and will be considered for appointment at a lower level.

Tenure:

Indefinite with superannuation.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 440/299 should reach The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maitlands Street, LONDON WC2R 3EH by 27th October 1978.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A.

7279(A)

An equal opportunity employer

Director of Research Laboratories

An experienced leader for one of the world's premier establishments in Mineral Processing, Extraction Metallurgy and Earth Sciences research.

The Research Laboratories of the Anglo American Corporation are located in Theta Township, a concentration of research establishments 5km from the business centre of Johannesburg.

The work embraces research and development concerned with most of the Corporation's mineral-related activities. Its achievements, in particular in relation to mineralogy, extraction metallurgical processes and exploration techniques, place the Laboratories among the world's leaders in these spheres.

The services provided to various of the Corporation's worldwide operating and exploration companies cover the fields of analysis, environmental protection, geology and mineralogy among others. Allied activities include the improvement of existing processes and the development of new ones, mineral identification and the troubleshooting of technical problems in operating companies and plants. Some of our work is concerned with pure science; some with sophisticated instrumentation activities, such as electron microprobe work and X-ray fluorescence. In short, we operate across a very broad spectrum.

The Director of the Research Laboratories will be expected to maintain active liaison and collaboration with the operating companies, and most particularly to identify future problem areas, and to initiate both fundamental and applied research aimed at achieving economically-viable solutions to them. Working through a highly-skilled technical management team, his role will be one of vision, guidance and resource-management.

He will not succeed in this task if he does not already possess an outstanding innovative record in a field or fields closely related to our own. We would expect him to be a skilled manager of human, financial and material resources, and probably to have had some experience in a production environment.

The benefits associated with this senior position will be negotiated. They will include full relocation expenses, and housing finance.

Candidates should send a detailed curriculum vitae to Dr. M. G. M. Atmore, Anglo Charter International Services Limited (Appointments Division), 40 Holborn Viaduct, London EC1P 1AJ. (7215A)

Head Office

Anglo American Corporation
OF SOUTH AFRICA LIMITED

MAX-PLANCK-INSTITUT
für molekulare Genetik, Berlin (West Germany)

BIOCHEMIST

with Ph.D. degree or equivalent, required for one year in the first instance to work on the blue-light photodifferentiation of *Phycomyces*.

Experience with oxygenases and/or Vitamin A would be an advantage.

Employment to start January-February 1979. Salary on the scale DM 19,000 to DM 30,000 (tax free) depending on experience and family status.

Applications with full curriculum vitae and the names of at least two references to Dr V. E. A. Russo, Max-Planck-Institut für molekulare Genetik, Ihnestr. 63/73, D-1000 Berlin 33. 7232(A)

TECHNICIAN/RESEARCH OFFICER

required at our Tumour Immunology Unit at University College to assist Dr M. Feldmann with immunological experiments involving tissue culture and biochemical techniques and some animal work. H.N.C. or Degree plus relevant laboratory experience. Salary range £3,615 to £5,256 including London Weighting. For application form and further information write or telephone Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields WC2 on 242 0200 ext. 305, quoting reference no: 288/78. 7260(A)

UNIVERSITY OF READING DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

Research Demonstratorship

Applications are invited from graduates in Biochemistry, Physiology or other related subjects, who would normally have an upper second class Honours degree, for a Research Demonstratorship to carry out research for a higher degree in the following subject:

The influence of hormonal status, species and sex differences on the metabolism of organochlorine compounds.

The support is for three years with the possibility of an extension and the duties include up to ten hour demonstrating per week during term time.

Enquiries and/or applications including the names of two academic referees, should be addressed to Professor G. M. H. Waites, Department of Physiology and Biochemistry, University of Reading, Whiteknights, Reading RG6 2AJ. Telephone Reading 85123 extension 7675 (Ref. T.N. 63A). 7257(A)

DIRECTOR BUFFALO MUSEUM OF SCIENCE

Chief Administrator of a collection oriented natural history museum founded 1861. Major responsibilities include long-range planning for preservation and exhibition of collections; direction and recruitment of professional and non-professional staff; budget and fund raising; supervision of publication, research and education programs. Staff of 60, budget \$5 million.

The Board of Managers is looking for a strong leader with the vision to realise the potential of distinguished collections, an active education program and a newly renovated building. Experience in museum administration and funding, and an established reputation in a scientific or scholarly research field are desired. Salary commensurate with experience. Applications to the Search Committee, Buffalo Museum of Science, Buffalo, New York, 14211. 7258(A)

TECHNICIAN/RESEARCH OFFICER

To assist with biochemical research at our Mill Hill Laboratories NW. Experience in nucleic acid research or a closely related field would be an advantage. H.N.C. or degree plus years laboratory experience. Salary range £3,615 to £5,257 including London Weighting. For application form and further information write or telephone, quoting reference no: 286/77 to Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields WC2 on 242 0200 ext. 305. 7261(A)

UNIVERSITY OF OXFORD LABORATORY OF MOLECULAR BIOPHYSICS POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a M.R.C.-supported postdoctoral research assistantship in biochemistry for years to work on structure-function relationships of glycogen phosphorylase b in close collaboration with the X-ray crystallography group in Oxford. Preference will be given to candidate with experience in enzymology or protein biochemistry.

Applications stating research experience and the names of 2 referees should be sent to Dr L. N. Johnson, Laboratory of Molecular Biophysics, South Parks Road, Oxford OX1 3P, from whom further details may be obtained. 7239(A)

POLYTECHNIC
DEPARTMENT OF
BIOLOGICAL SCIENCES
Readvertisement
S.R.C. POSTDOCTORAL
RESEARCH ASSOCIATE
in
NEUROPHYSIOLOGY

Required for 2-year contract to work on a project financed by S.R.C. on the role of central neurones in the control of body wall musculature in the leech. Experience of intracellular recording is necessary and an interest in pharmacology desirable.

Candidates should already have a doctorate.

Salary within the range £3,510 to £3,711 according to qualifications and experience.

Application forms from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by October 13, 1978.

Please quote Reference B36.
7276(A)

UNIVERSITY OF
EDINBURGH
DEPARTMENT OF PHYSICS
POSTDOCTORAL
RESEARCH FELLOW

A Postdoctoral Research Fellow is required to work with a group studying nuclear disintegration using real and virtual photons in the range 10–160 MeV at the Kelvin Laboratory 160 MeV electron linear accelerator. Applicants should have several years experience of working in the field of nuclear physics or a related field. An appointment will be made for 18 months in the first instance.

Salary will be on the range 1A £3,660 to £4,365 per annum, according to age and experience.

Applications, together with a curriculum vitae and the names and addresses of two referees should be sent to Dr D. Branford, Physics Department, James Clerk Maxwell Building, The King's Buildings, Mayfield Road, Edinburgh EH9 3JZ, before November 1, 1978. Please quote Reference 5055.
7274(A)

UNIVERSITY COLLEGE
LONDON
DEPARTMENT OF
PHYSICS AND ASTRONOMY
POSTDOCTORAL
RESEARCH ASSISTANT IN
HIGH ENERGY PHYSICS

Required as soon as possible after October 1, 1978 to work on an experimental programme using the S.P.S. Accelerator at CERN, Geneva. The successful applicant will probably be based in Geneva and will help in the running of a large experiment designed to study 2-Body exclusive hadronic processes at very high energies, using large double-arm spectrometer. Salary will be in range £4,858 to £5,342 p.a. inc London Allowance plus U.S.S. If based in Geneva, fares, housing and additional allowances are provided.

Applications, giving details of qualifications and curriculum vitae and names and addresses of 2 referees, should be sent to Dr B. G. Duff, Department of Physics and Astronomy N), University College London WC1E 6BT as soon as possible.
7248(A)

CSIRO AUSTRALIA Chief of Division Division of Chemical Physics Clayton, Victoria

Applications are invited from scientists who have an established record of personal research achievement and leadership, for the position of Chief, Division of Chemical Physics. The position has become vacant on the retirement of the foundation Chief, Dr A. L. G. Rees.

CSIRO is Australia's largest and most comprehensive research organisation, having approximately 7000 employees of whom 2400 are research and professional scientists. Its broad charter covers research into problems of primary and secondary industries and also such fields of community interest as human nutrition, the environment and the development and use of natural resources. The Organization has 42 Divisions or independent Units dispersed throughout Australia.

The Organization is at present implementing the Government's decisions relating to the recommendations of the Independent Inquiry into CSIRO. Applicants may therefore wish to read the Inquiry Report; in addition they may find it helpful to read the statements made in Parliament on 11 May 1978 by the Prime Minister and the Minister for Science relating to the Government's decisions.

The Division of Chemical Physics, located in Clayton, a suburb of Melbourne, Victoria, adjacent to Monash University, has a staff of 103, which includes 56 scientists and engineers. Research in Chemical Physics was established in 1944 in the Division of Industrial Chemistry to meet the urgent demand for the introduction to Australia of major chemico-physical methods which were being rapidly developed overseas. The Division of Chemical Physics was formed in 1958. Throughout its history the Division has made contributions of a basic character to scientific knowledge, combined with development programs related to scientific instruments.

The current research of the Division is centred on a number of specialised fields, including atomic absorption and resonance spectroscopy, molecular spectroscopy, specialised optics (including optical diffraction gratings), mass spectroscopy, magnetic resonance spectroscopy, electron diffraction, electron microscopy, X-ray diffraction, solid state chemistry, crystal defect physics, theoretical chemistry, and development of scientific instruments and techniques.

A Chief of a Division is responsible to the CSIRO Executive for the development, scientific direction and integration of the research programs of the Division, and is encouraged to promote active collaboration with other Divisions, industry and various research bodies working in associated areas.

The Executive has recently reviewed the objectives, work and management of the Division of Chemical Physics, and the new Chief would be expected to take cognizance of the recommendations arising from the review.

The salary for the position is negotiable but will not be less than \$A33,052 p.a.

The terms of the appointment will be discussed with the short-listed applicants at interview. The appointee would be eligible to contribute to the Commonwealth Superannuation Scheme.

Further information on the Division is in a booklet available on request from the Secretary, CSIRO, at the address below.

Dr Hill W. Worner, a member of the CSIRO Executive, is Chairman of the appointment committee for this position and would be pleased to discuss the position with potential applicants. He would also be pleased to receive advice concerning this appointment from people with a particular interest in it but who do not wish to be considered for it. Dr Worner can be contacted at the address below.

Applications stating full personal and professional details and names of at least two professional referees and quoting reference number 582/155 should reach:

The Secretary, CSIRO, P.O. Box 225, Dickson ACT 2602, AUSTRALIA, by 31 October 1978.
7278(A)

Nature Conservancy Council Higher/Senior Scientific Officers

Salary Scales:

Higher Scientific Officer £4,101-£5,448

Senior Scientific Officer £5,154-£6,898

An allowance of £465 p.a. is also payable for the London based posts

Applications are invited for the following posts with the Nature Conservancy Council

1. Wildlife Advisory Branch—HSO/SSO based in London

The person appointed will provide the Branch with a scientific information resource on the status of individual species, their habitats and research related to them both nationally and in connection with the Branch's responsibility for the Convention on International Trade in Endangered Species (CITES) and other international matters concerning species. He/she will also provide scientific support within the Branch in the preparation and drafting of papers, replies to correspondence, initial examination of proposals on species conservation, briefing for and preparation and servicing of meetings.

2. Wildlife Advisory Branch—HSO based in London

The person appointed will provide general scientific support to the Branch and be the focus within the Branch for specialist advice on one or more species or groups, habitats and other specific areas of the work of the Branch, be responsible for the general co-ordination and oversight of the work funded by the Branch by contract and casual labour and will interpret new scientific knowledge into an action strategy where it is appropriate to the work of the Branch.

3. Scientific Development and Advisory Unit, Scotland Advisory Officer: Rural Land Use and Planning— HSO/SSO based in Edinburgh

The person appointed should preferably have experience in the field of rural land use. The main emphasis of the work will be on broad issues related to the impact of major land uses such as agriculture, forestry, fisheries and game management, recreation and tourism, and water resource development on the natural environment, with specific reference to nature conservation interests. The Advisory Officer will be required to represent the Nature Conservancy Council on inter-departmental committees dealing with issues of rural land use. A knowledge of technical practice in agriculture or forestry would be an advantage.

4. Scientific Development and Advisory Unit, Scotland Advisory Officer: Impact of Industrial and Urban Development—HSO/SSO based in Edinburgh

The person appointed should preferably have experience in the field of environmental impact studies. The main emphasis of the work will entail the development of expertise and the giving of advice to NCC Regional and Scottish Headquarters staff on the impact on the natural environment of major industrial and urban developments in Scotland with special emphasis on the energy industry, notably North Sea Oil and Gas, and allied petrochemical developments, but also including major mineral extraction and quarrying developments. This will involve close study of the technical requirements of the industries concerned and of developments in environmental protection in relation to them. Close liaison with industry and government regulating agencies will be essential.

A current driving licence is essential for posts (3) and (4)

Age and Qualifications

All candidates should have a first or second class honours degree, or equivalent, in biology, botany, zoology, geography or geology.

Higher Scientific Officers: Candidates should be under 30 years of age and have at least two years relevant postgraduate experience.

Senior Scientific Officers: Candidates should be between 25 and 32 years of age and have at least 4 years relevant postgraduate experience.

Application forms and further details are available from Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs PE18 6BU (Tel: 0480 56191)

Closing date for receipt of completed application forms 27 October 1978.

7224(A)

THE MEDICAL RESEARCH COUNCIL OF NEW ZEALAND DIRECTOR

Applications are sought for appointment to the position of Director of the Medical Research Council of New Zealand, to replace Dr J. V. Hodge, M.D., F.R.A.C.P., who has indicated his wish to withdraw from the Directorship in mid-1979.

The Council aims to support the balanced development of medical and related biological research in hospitals, universities, or Council's own units, from funds largely provided from a Government grant. Standing committees assist Council in evaluating applications for research grants and fellowships, and provide leadership and expertise in fields of special need or concern. Administration of Council's activities is carried out at present from its office in Dunedin.

Council is seeking a person with proven experience in medical or related biological research and administration. The position is equivalent to an appointment at university professorial level.

Intending applicants are invited to write to the Secretary of the Council or to the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further information and the details required in an application. Applications should reach the Secretary of the Council at P.O. Box 6063, Dunedin, New Zealand, not later than January 31, 1979. Council reserves the right to make no appointment or to appoint by invitation.

7266(A)

CORNELL UNIVERSITY

Applications are invited for a post-doctoral research associate position in our common project, procaryotic gene expression in yeast. This position requires Ph.D. in molecular biology or in molecular genetics and research experiences with plasmids, restriction enzymes and DNA sequencing. The position will be available November 1, 1978.

Send curriculum vitae and three references to:

Dr G. R. Fink, Department of Genetics, 216 Bradford, Cornell University, Ithaca, N.Y. 14853.

Dr A. A. Szalay, Department of Biochemistry, Molecular and Cell Biology, Wing Hall, Cornell University, Ithaca, N.Y. 14853.

Affirmative action/equal opportunity employer. 7263(A)

UNIVERSITY OF BRISTOL POSTDOCTORAL RESEARCH ASSISTANTSHIP in Theoretical Chemistry/ Theoretical Physics

Applications are invited for a SRC funded postdoctoral research assistantship, available for two years from October 1978, to study the theory of photodissociation processes. The project will be aimed at developing theoretical methods for describing and predicting the outcome of chemical photodissociation processes. The work will involve the use of molecular scattering theory techniques. No prior knowledge of scattering theory is necessary, but experience computing would be desirable. Initial salary in the range £3,883 to £4,311 per annum (scale under review).

Applications, with curriculum vitae and the names of two referees, to: Dr G. G. Balint-Kurti, School of Chemistry, Bristol University, Bristol BS8 1TS, U.K. 7240(A)

THE UNIVERSITY OF MANCHESTER TECHNICIAN

required with a minimum of O.N.C. or equivalent qualification and laboratory experience to work in the Department of Obstetrics and Gynaecology, University Hospital of South Manchester. The work will involve organ culture of female reproductive tissue, histology and autoradiography. Assistance will also be required in the establishment of new research methods into human fertility. Suitable candidates may be considered for registration for higher qualifications.

Salary scale £2,688 to £3,060 p.a. Applications, including a curriculum vitae and the names and addresses of two academic referees should reach the Secretary, Department of Obstetrics and Gynaecology, Research and Teaching Block, University Hospital of South Manchester, West Didsbury, Manchester M20 8LR by no later than October 6, 1978. 7262(A)

LUDWIG INSTITUTE FOR CANCER RESEARCH (LONDON BRANCH)

(In association with the Royal Marsden Hospital and the Institute of Cancer Research, Sutton, Surrey)

RESEARCH ASSISTANT

required to undertake laboratory duties with a clinical and fundamental research programme on hormone receptors in breast cancer. Familiarity with work in this field is not essential but candidates will be preferred with two or three years proven experience in laboratory techniques and with higher qualification in Chemistry/Biochemistry. Starting salary probable within current range of £3,580-£4,680, according to age and qualifications. Further particulars may be obtained from The Secretary, Ludwig Institute for Cancer Research (London Branch), The Hadow Laboratory, Clifton Avenue, Sutton, Surrey SA5 8PX. 7236(A)

St Paul, Minnesota, U.S.A.
DEAN

Applications and nominations are invited for the position of Dean of the College of Veterinary Medicine. Candidates must be veterinarians and should have demonstrated ability in scientific research and teaching and an understanding of the service aspects of veterinary medicine. Previous experience in practice, academic, industrial, or governmental veterinary medicine is required.

The Dean provides leadership for all aspects of the educational, research and service functions of the faculty and has budgetary responsibility for the college, which has 82 faculty members, 125 civil service personnel and approximately 320 students enrolled in the D.V.M. program and 100 students in graduate and residency programs.

Applications should include vitae and names and addresses of references and should be sent to Dr A. J. Linck, Chair, Advisory Selection Committee, 213 Morrill Hall, University of Minnesota, Minneapolis, MN 55455. They must be postmarked no later than November 27, 1978.

The University of Minnesota is an equal opportunity educator and employer. 7228(A)

ROTHAMSTED
EXPERIMENTAL STATION
Harpenden, Herts AL5 2JQ
PLANT PHYSIOLOGIST

to work in the Soils and Plant Nutrition Department on investigations into the distribution and properties of crop roots in the field, in relation to their absorption of nutrients and water.

Qualifications: First or upper second class honours degree in botany or biology, with good background in chemistry. Preference will be given to candidates with a doctorate or other postgraduate experience in the field of plant physiology or ecology.

Appointment in grade of Scientific Officer (£3,294 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) starting salary depending on experience. At least two years' relevant post qualifying experience is required for appointment at H.S.O. Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees, and quoting Ref. 351 by October 27, 1978. Further particulars on request. 7233(A)

UNIVERSITY OF
STRATHCLYDE

Applications are invited from experimental or theoretical physicists with postdoctoral research experience for a LECTURESHIP in the DEPARTMENT OF NATURAL PHILOSOPHY. Applicants should have research interests related to the work of the Department in laser/plasma physics. The successful candidate will be required to participate in general undergraduate and postgraduate teaching in physics as well as in the research interests of the Department.

Salary scale £3,883 to £7,754 with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 49/78) and enclosing a self-addressed envelope (9"x4") may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by October 9, 1978. 7227(A)

Western Australia

MYCOLOGIST/PLANT PATHOLOGIST TO WORK ON PHYTOPHTHORA CINNAMOMI RANDS

CONTRACT APPOINTMENTS

Department of Conservation and Environment

SALARY:

\$A15,286

QUALIFICATIONS AND EXPERIENCE:

Tertiary qualifications with postgraduate research experience in soil mycology, plant root diseases or plant pathology essential. Postdoctoral experience may be an advantage.

DUTIES:

Phytophthora cinnamomi Rands is currently causing extensive damage to the jarrah forest in Western Australia. To date over 200,000 hectares of forest have been affected. The successful candidate will be expected to conduct research on the biology, epidemiology, detection and control of *Phytophthora cinnamomi* Rands. The appointee will be required to liaise and work closely with research personnel in the Commonwealth Scientific and Industrial Research Organization, the Forests Department and the Tertiary Institutions in the State under the general direction of a Supervisory Panel.

LOCATION:

Initially with Dr Andrew Glenn, School of Environmental and Life Sciences, Murdoch University, Perth, Western Australia.

CONDITIONS OF SERVICE:

The successful applicant will be required to enter into a contract with the Minister for Conservation and the Environment. The term of the contract will be for five years. Conditions applying under the contract will be the same as for temporary employees employed under the Public Service Act and include four weeks annual leave, cumulative sick leave and other general conditions applicable to temporary employees.

TRANSPORT AND REMOVAL ASSISTANCE:

The cost of first class air fares incurred by the appointee, wife and dependent children under the age of sixteen years, plus a reasonable amount for removal of essential personal and household effects, subject to the appointee entering into an agreement to remain in the employ of the State for one to three years, according to assistance given. A single appointee will receive the cost of first class air fares. Some assistance towards the cost of removal of personal effects will be granted.

APPLICATIONS:

To state age, citizenship, qualifications and experience with the names of two referees to the Chairman, Public Service Board, 111 St. George's Terrace, PERTH, WESTERN AUSTRALIA 8000.

Closing: October 27, 1978

7273(A)

Technicians

Production and Research

There are currently several vacancies at our new production and research laboratories at Milton Keynes

Senior Technician - Drug Metabolism

To carry out Metabolism Studies in animals and man. Applicants must have a good general knowledge of most laboratory techniques. Previous experience could be advantageous. Qualifications required are BSc in Bio Chemistry, Biology or related subjects; MI Biol. or equivalent.

Technician - Drug Metabolism

To assist in Drug Metabolism Studies. Experience in this area would be desirable but not essential as on the job training would be given. Applicants must have 'A' levels, HNC, HND or equivalent.

Technician - Production

To assist with processes associated with the production of veterinary bacterial vaccines. Applicants should have HNC/HND or equivalent. Experience of microbiology or of production processing would be an added advantage.

These posts carry excellent salaries, our conditions of employment are first class and our benefits package is of the standard expected from a major international company.

Please write or telephone for an application form to:

Mrs. Sheila Matthews, Hoechst UK Limited, Walton Manor, Walton, Milton Keynes. Tel: Plneham 5068.

Hoechst

7225(A)

MEDICAL RESEARCH COUNCIL ELECTRON MICROSCOPIST

Applications are invited from graduates with a degree in Medicine, or Biological Sciences to develop a research programme into the mechanism of action of toxic substances. The successful candidate will be responsible for leading a group consisting of one other scientist (to be appointed) and two technicians together with research students and visiting scientists. He will also be responsible for promoting collaborative research with other members of the unit working Toxicological problems, either in the whole animal or in isolated cells cultured *in vitro*.

Salary on MRC scientific staff scales (non-clinical) depending on age and experience.

Apply in writing enclosing a full curriculum vitae and giving the name of two referees to the Director, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

MRC
Medical Research Council

7272(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF ATOMIC PHYSICS

Applications are invited from persons with postgraduate research experience for the post of DEMONSTRATOR in Atomic Physics. The Demonstrator would contribute to undergraduate teaching and conduct research in laser spectroscopy, high resolution spectroscopy or in experimental or theoretical aspects of atomic collisions. Well-equipped research programmes are active in each of these topics. The appointment will be for three years.

Salary will be at an appropriate point on the Grade 1B (Bar) scale £3,384 to £4,882 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Two copies of applications together with the names and addresses of three referees, should be lodged with the Registrar, The University, Newcastle upon Tyne NE1 7RU, not later than November 6, 1978. Please quote Reference N

7277(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

FACULTY OF SCIENCE DEPARTMENT OF BIOCHEMISTRY SENIOR TUTOR IN MICROBIOLOGY

Applicants should have a higher degree and teaching interests in Microbiology. The appointee will be expected to contribute to the teaching programme and to assist in preparation, supervision and assessment of practical classes in second-year general microbiology and third-year classes in microbiology, immunology and molecular genetics. The appointee will be required to participate in training PhD and Honours students in the research of the Department (primarily in collaborative ventures with the other staff).

Research in the Department (Head: Professor J. F. Williams) includes studies of the molecular basis of motility in slime moulds, protein and nucleic acid synthesis in arbovirus-infected cells, hydrogen generation by blue-green algae, R-plasmids in enteric bacteria, *Drosophila* genetics, intermediary metabolism, membrane structure and function, lymphocyte transformation.

Appointment as Senior Tutor is normally for one year in the first instance with the possibility of yearly renewal up to five years.

CLOSING DATE NOVEMBER 17, 1978

SALARIES Salary on appointment will be in accordance with qualifications and experience within the range Senior Tutor \$A13,083 to \$A14,987 per annum. Current exchange rates \$A1=£SUS1.15; 59p.

OTHER CONDITIONS Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Apsu), 36 Gordon Square, London WC1H 0PF 7267(A).

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) DEPARTMENT OF HAEMATOLOGY

Applications are invited for a RESEARCH OFFICER

to work on ferritin variants in leukaemia. The project involves the tissue culture of lymphocytes and the purification and characterisation of white cell ferritins. Experience of preparative protein techniques is essential and a working knowledge of immunological and cell culture methods is desirable.

Candidates should hold a good degree or equivalent in a biological science and have particular interest in biochemistry. The project is funded by the M.R.C. for a period of 3 years. Salary will be on the scale for University Research and Analogous Staff Grade 1B (£3,384 to £4,882 per annum under review).

Applications, which should take the form of a brief curriculum vitae with the names and addresses of two referees, should be sent to the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN (quoting ref No H24/2/28).

The Department may be visited by appointment with Professor Jacobs (Tel No. Cardiff 755944 ext 2375), 7237(A).

**UNIVERSITY OF OXFORD
NUFFIELD INSTITUTE
FOR MEDICAL RESEARCH
POSTGRADUATE
RESEARCH ASSISTANT**

The post involves work on fetal growth and development, particularly in sheep and monkeys. Experience in immunoassay procedures preferred.

Applicants should possess a good honours degree in Physiology or related subject. The post is available immediately and is funded to December 1983. Salary on Oxford Research Staff 1B scale, £3,189 to £5,282 p.a. (subject to review).

Letters of application, together with curriculum vitae and the names of two referees, should be sent to:

The Administrator
Nuffield Institute
for Medical Research
Headley Way
Headington
OXFORD OX3 9DS

7275(A)

**COMMONWEALTH
AGRICULTURAL BUREAUX**

Vacancy for
DIRECTOR

**COMMONWEALTH
BUREAU OF
NUTRITION**

Buckburn, Aberdeen

The vacancy occurs because of the retirement of Miss D. L. Duncan, B.Sc., Ph.D.

The main work of the Bureau is to collect and disseminate to research workers information on the nutrition of man and animals and its implications for agriculture and human welfare. This is done largely through the medium of two journals (Nutrition Abstracts and Reviews Series A—Human and Experimental, Series B—Livestock Feeds and Feeding), which cover in the form of abstracts, relevant scientific papers published world-wide. The abstracts are regarded by scientists as an indispensable source of reference. Like all others in the CAB series, the two journals in machine-readable form are accessible online through the DIALOG system.

The Director is responsible for maintaining the high standards of the journals and for the day-to-day management of the Bureau.

Applicants with appropriate scientific qualifications should have had experience in agriculture, veterinary or human medicine, or in one of the biological sciences basic to nutrition. Familiarity with administration is required. Experience in editorial work and the production of scientific publications would be an advantage. A knowledge of European languages other than English is desirable.

The scale for the post is £6,609 to £9,450 per annum. The starting salary will relate to qualifications and experience. The post is pensionable.

The normal retiring age is 60, but this may be extended to 65.

Application forms and full particulars can be obtained from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Closing date: October 31, 1978.

7234(A)

**UNIVERSITY OF ASTON
IN BIRMINGHAM**

**DEPARTMENT OF
BIOLOGICAL SCIENCES
DIABETES RESEARCH**

Applications are invited for a

**POSTDOCTORAL
RESEARCH FELLOW**

to join the Experimental Diabetes Research Group.

The project concerns the preparation and efficiency of microencapsulated insulin. Chemically, biochemically or pharmaceutically trained candidates with experience of and interest in the biological applications of polymers would be preferred.

The appointment is for a period of three years and the salary will be within the range £4,382 to £4,882 per annum.

Preliminary enquiries may be made to Dr T. Atkinson (Tel. 021 359 3611, Ext. 423).

Application forms and further details can be obtained from the Staff Officer (quoting Ref. 303/6), University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET to whom applications should be forwarded not later than October 27, 1978.

7221(A)

**UNIVERSITY OF GLASGOW
RESEARCH ASSISTANT**

DEPARTMENTS OF

**SURGERY AND BIOCHEMISTRY,
GLASGOW ROYAL INFIRMARY**

Applications are invited for the post of RESEARCH ASSISTANT in an interdisciplinary group investigating the production of foetal antigens by human tumours. The post is suitable for a graduate in biochemistry or related subject. Experience in radio-immunoassay techniques would be an advantage. The successful candidate will work in the new Department of Biochemistry, Glasgow Royal Infirmary. The appointment is funded by the Cancer Research Campaign and is tenable for one year. The salary will be within the University Research Assistant scale (£3,660 to £4,130 per annum presently under revision). The appropriate superannuation scheme applies. Starting date by agreement.

Further information can be obtained from Dr J. G. Ratcliffe, Department of Biochemistry, Royal Infirmary, Glasgow G4 0SP (Tel. 041-552 3535, Ext. 3275) to whom applications including curriculum vitae and the names of two referees should be sent within two weeks of the appearance of this advertisement.

In reply, please quote Ref. No. 4241(M). 7242(A)

**UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY**

Applications are invited from Chemists or Chemical Physicists for an S.R.C. Postdoctoral Senior Research Assistantship for seventeen months from as soon as possible to work in collaboration with Dr J. Yarwood on the interaction and dynamics of hydrogen bonded systems in the liquid phase. These studies which include infra-red, far-infra-red, Raman and neutron scattering studies are also supported by a N.Y.A.T.O. research grant and would be carried out at Durham, the Technical University, Braunachweig and at A.E.R.E., Harwell. Some experience in one branch of molecular spectroscopy is essential and an interest in the chemical physics of molecular motions and interaction in the liquid phase would be an advantage.

Initial salary in the range £3,660 to £4,130 p.a. (under review) on National Research Range 1A plus superannuation.

Applications (3 copies) naming three academic referees should be sent by October 6, 1978 to The Registrar and Secretary, Science Laboratories, South Road, Durham DH1 1LE. 7255(A)

MRC

Medical Research Council

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Division of Biochemistry

Applications are invited for the post of

HEAD OF THE DIVISION OF BIOCHEMISTRY

The Division at present has a staff of 31 and its main areas of activity are in cell membrane structure and function, regulation of protein biosynthesis and in ribosome and nuclear biochemistry. The future form of the Division has yet to be decided and can be discussed with potential candidates.

The post is a permanent one carrying a salary within the professorial range.

Enquiries should be addressed to the Director, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA to arrive not later than 31st October 1978.

7235(A)

UMIST

Research and Teaching Posts in
Building Science and Technology

UMIST has an active, developing programme of research into environment, services, energy conservation and production problems of buildings. Applications are invited from candidates of either sex for up to six temporary appointments which could be of up to two or three years duration in the following fields:

1. Building Services Unit

This Joint Unit has recently been established between the Department of Building and the Control Systems Centre to promote investigation into the thermal dynamics and the control performance of buildings and building environmental services.

2. SRC-supported project: Investigations of the thermal and moisture dynamics of buildings

This is a large scale project which is concerned with a number of aspects of building performance: large-scale laboratory investigations of the thermal response of buildings, heat and moisture flow in building materials, and field studies in existing buildings.

In total five research assistantships and one temporary lectureship are available. The temporary lectureship will be specifically connected with the Joint Unit. Both recent graduates and those with research experience and higher degrees are invited to apply. The posts would be of interest to graduates in, for example, Mechanical or Electrical Engineering, Physics, Chemistry, Materials Science or Building Science.

Salary for Research Assistants on Range 1B (£3,384-£4,882) or Range 1A (£3,883-£8,555) and for Lectureship on scale—£3,883-£7,754.

Application forms and further details may be obtained from the Registrar, UMIST, PO Box 88, Manchester, M60 1QD, by quoting ref. BU1/161/AI.

7238(A)

Department of Health and
Social Security

Pharmacist/Chemist

The British Pharmacopoeia Commission is based in London and is responsible for all standards published in Britain for substances and articles used in human and veterinary medicine, and collaborates in the publication of the European Pharmacopoeia. It is aided by committees comprising leading experts in the medical, chemical, pharmaceutical and allied fields.

The scientist appointed will become familiar with all aspects of the work associated with the Commission's activities and will act as secretary to a number of Committees and Panels. The work will involve the initial collection of data for the preparation of specifications to control identity, purity and potency, as well as minute writing and preparation of copy for printing.

Candidates, normally aged under 30, should preferably have a good honours degree in pharmacy, chemistry, biology or related discipline, combined with at least 2 years' postgraduate experience, and have some knowledge of the quality control of medicines.

Appointment as Higher Scientific Officer (£4560-£5910) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 20th October 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/11/KD. 7254(A)

RODENT TOXICOLOGY

If you are a graduate (or equivalent) with some years' experience in toxicology and are not currently earning the salary which toxicologists should command these days, or if you are ready for a career step, get in touch. We may just make you an offer you cannot refuse and might not be able to match elsewhere.

Our laboratories are situated in rural East Lothian convenient for coast and country yet close to the city of Edinburgh. The fringe benefits which are significant will include, where appropriate, a generous rota allowance, and a very substantial relocation package.

Application forms, quoting ref. 2323, are available from Miss J. M. Dunbar, Inveresk Research International, Inveresk Gate, Musselburgh, EH21 7UB, Tel 031 665 6881. 7220(A)

GROUP MANAGER R & D HEALTH MARKET

For many decades we have numbered among the well-known and successful German pharmaceutical companies whose many ethical pharmaceuticals contribute markedly to therapy. We are now in the process of intensively engaging ourselves in the health markets with the intention of making a substantial contribution to the general increase of human health through new physiological concepts and products. For this challenging undertaking we seek the Group Manager Research and Development who will lead and motivate our R & D team and provide the impetus and guidance we need to realise our plans.

The position requires a NUTRITION PHYSIOLOGIST with a scientific or medical training who possesses good personal contacts within the circles of his colleagues at universities and research institutes, is theoretically familiar with current problems in nutrition physiology, has experience in the planning and realisation of practical scientific work, and is capable of presenting new developments in the area of dietary products in a scientifically correct and pedagogically attractive form. In addition, if he has some industrial experience in the area of specialty diets and essential nutrition components, knows the relevant legal regulations and understands enough of the market situation in order to be able to speak with authority to his partners in marketing, he will be able to successfully achieve our goals.

To find the right man for this position is of crucial importance to us, we have therefore put together an appropriately attractive package. This as well as the other important details we would like to discuss with you in person. Please contact us through our consultant who will treat your inquiry in utmost confidence. Mrs R. Nicolai will be at your disposal for a first telephone contact during normal office hours under the following number:

0 1049 211-57 90 97

A letter addressed to her at the address given below will also reach us without delay. INTERELECT Unternehmensberatung, Kaiser-Wilhelm-Ring 12, D-4000 Düsseldorf 11 7256(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the temporary post of postdoctoral RESEARCH FELLOW for a fixed period of 3 years. The post is for research into the organisation and structure of the major protein species of myelin. Experience in the fields of protein chemistry or membranes would be an advantage but is not essential.

Salary in the range £3,883 to £4,882 (under review) on the 1A Scale for Research and Analogous Staff according to age and experience.

Applications, enclosing a curriculum vitae and the names of two referees, should be sent to Dr J. Findlay, Department of Biochemistry, The University of Leeds, Leeds LS2 9JT. Closing date for applications October 19, 1978. 7218(A)

UNIVERSITY OF SHEFFIELD

TECHNICIAN (Grade 5)

required for the Department of Biochemistry. The person appointed will be required to operate the University Amino Acid Analyser service. Applications are invited from graduates or non-graduates with H.N.C. Salary on scale £3,186 to £3,720 per annum.

Please write to the Administrative Officer (Personnel), (Ref. S1058/N), The University, Sheffield S10 2TN 7230(A)

THE UNIVERSITY OF MANCHESTER CHAIR OF BIOCHEMISTRY

Applications are invited for a new established additional Chair of Chemistry in the Faculty of Science. The existing Chair in the Department is held by Professor G. R. Bar. Particulars of the appointment to be obtained from the Registrar. Applications (two copies, one suit for photocopying) giving full details of qualifications, experience, research etc., and the names and addresses of three persons to whom reference may be made should be sent to Registrar, The University, Manchester M13 9PL by November 14, 1978. Quote ref 178/78/N 7216(A)

THE UNIVERSITY OF MANCHESTER DEPARTMENT OF PSYCHIATRY

RESEARCH FELLOW IN NEUROPHYSIOLOGY

Applications are invited for this post (tenable until December 1980) to study the electrophysiological consequences of adrenoceptor activation in mammalian nerve cells using intracellular recording techniques. The appointee will collaborate with a small research team working within the field of cellular neuropharmacology. Applicants should possess a Ph.D., and have research experience with neurophysiological techniques. Prefer starting date: January 1.

Salary range p.a. £3,883 to £6,500. Applications with curriculum vitae and the names of two referees should be sent before October 31, to Dr Szabadi, Department of Psychiatry, University of Manchester, Stopford Building, Oxford Road, Manchester M13 9PT. 7166(A)

VIROLOGIST

The National Institute for Biological Standards and Control is a multidisciplinary Institute concerned with the standardisation and control of biological substances used in medicine and associated research work. The Institute is a WHO International Laboratory for biological standards.

We are seeking to appoint a scientist in the Institute's Division of Viral Products to carry out research work on viral vaccines aimed at the development of improved methods for their standardisation and control.

The position provides an excellent opportunity to contribute to the active virological research programme of the Division which is well equipped for modern techniques.

Applicants should hold a PhD or equivalent qualification in medicine or veterinary science and should have recent research experience in biochemical or immunological aspects of animal virology.

Salary will be on the universities non-clinical lecturing scales.

Application forms and further details of the post are available from Peter Collingridge, National Institute for Biological Standards and Control, Holly Hill, Hampstead, NW3 6RB. Telephone: 01-435 2232, ext 211. Please quote Reference No: 0148. 7231(A)

NIBSC

National Institute for Biological Standards and Control

UNIVERSITY OF GLASGOW POSTDOCTORAL POST

Applications are invited for a post-doctoral position in an MRC-supported programme studying **Molecular and Genetic Control of Antibody Formation**. The emphasis of the group is on application of recombinant DNA techniques to molecular genetics of antibodies. Experience in any aspect of recombinant DNA or DNA sequencing methodologies would be an advantage. Position available immediately and is enable for up to five years from date of appointment.

Salary scale: £3,384 to £7,754. Applications with curriculum vitae and names of two referees as soon as possible to: Professor A. R. Williamson, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ. In reply please quote Ref. No. 233(M). 7243(A)

QUEEN MARY COLLEGE University of London CHEMISTRY DEPARTMENT Applications are invited for a GRADUATE RESEARCH ASSISTANTSHIP

or work with Professor R. Bonnett and Dr M. B. Hursthouse on the isolation and structure of bile pigments. The post, which is for 2 years, would suit candidates with experience of isolation techniques and an interest in medical biochemistry. Initial salary in grade (under review) £3,384 to £3,883 p.a. plus £450 London Allowance. Please apply by letter, giving age, qualifications, experience and names of 2 referees, to The Registrar, N, Queen Mary College, Mile End Road, London E1 4NS, not later than October 15. 7253(A)

UNIVERSITY OF ST ANDREWS LECTURESHIP IN MARINE BIOLOGY

Applications are invited for a lectureship in Marine Biology to teach in a newly instituted Honours course of Marine Biology in the Gatty Marine Laboratory of the University of St Andrews.

The course is due to start in October 1979 but the appointment will commence April 1, 1979 to allow the appointee to assist in planning and organisation. Preference may be shown for an experimentalist with research interests in plankton, but no candidate in any other field is excluded from applying.

Salary at appropriate point on scale £3,660 to £7,308 (under review), starting salary probably not above £5,282, plus F.S.S.U./U.S.S.

Applications (two copies preferably in typescript) with the names of three referees should be lodged by November 3, 1978 with the Establishments Officer, The University, College Gate, St Andrews, Fife, from whom further particulars may be obtained. 7249(A)

APPOINTMENTS WANTED

BIOCHEMISTRY TECHNOLOGIST, A.I.M.L.S.

25, with excellent academic record, seeks position in continental Europe, Australasia or North America. Prefer non-clinical field (e.g. research, industrial, publishing). Box No. 7265(B), c/o Macmillan Journals Ltd., 3 Dyers Buildings, London EC1N 2NR. 7265(B)

THE UNIVERSITY OF LEEDS DEPARTMENT OF PLANT SCIENCES

GRADE 5 TECHNICIAN IN ELECTRON MICROSCOPY

Applications are invited for the above post. The person appointed will be in charge of the maintenance and preparation work concerned with a research and teaching facility which includes three transmission electron microscopes (a Siemens Elmiskop 1A, an A.B.I. EM6B and a Siemens 102), a scanning electron microscope (Cambridge S6000) and ancillary equipment.

Applicants should possess an H.N.C. or equivalent qualification and have had about 10 years relevant experience.

Salary on the scale £3,186 to £3,720 a year.

Applications with the names of two referees and full details of qualifications and practical experience should be submitted by October 6, 1978 to The Secretary, Department of Plant Sciences, Baines Wing, The University, Leeds LS2 9JT. 7259(A)

FELLOWSHIPS

UNIVERSITY OF BRISTOL POSTDOCTORATE RESEARCH FELLOWSHIP

Applications are invited for a post-doctorate fellowship established to investigate the synaptic mechanisms regulating the peptidergic neurones of the magnocellular nuclei of the rat hypothalamus. Previous experience of electrophysiological recording from the CNS is required, and some expertise in the application of iontophoretic methods is desirable.

The appointment is funded by the Medical Research Council for two years from October 1, 1978. Salary will be determined by age and experience (minimum £4,382 per annum at age 26—scale under review).

Applications giving details of age, qualifications and experience, together with the names of two referees, should be sent by October 16 to Dr D. W. Lincoln, The Medical School, University Walk, Bristol BS8 1TD, from whom further particulars are available (Bristol 24161, ext. 557). 7241(E)

UNIVERSITY OF DUBLIN TRINITY COLLEGE Chemistry Department

Applications are invited for three postdoctoral fellowships in this Department, funded by the National Board of Science and Technology. The salary will commence at £3,762 p.a., and the appointments will be for one year in the first instance, with a possible extension for two further years. Appointments can be made from October 1, 1978.

The projects are as follows:

- In Organic Chemistry (in collaboration with Dr P. H. Boyle) to study the chemistry of quinonoid compounds used as food additives. This project will also receive support from industry.
- In Inorganic Chemistry (in collaboration with Drs C. J. and D. J. Cardin) for the study of catalytically active organometallic derivatives of transition metal cluster compounds. The project will involve synthesis, structure determination, and study of catalytic behaviour. Experience in organometallic or inorganic chemistry is required, and knowledge of, or an interest in learning aspects of X-ray crystallography would be an advantage.
- In Organic Chemistry (in collaboration with Professor T. B. H. Murray) to study the photochemical intramolecular addition of olefinic bonds to cyclic enones. Experience in synthetic and/or photochemistry would be an advantage.

Applications with curriculum vitae and the names and addresses of two referees should be sent to: The Establishment Officer, West Theatre, Trinity College, Dublin 2. 7217(E)

FLINDERS UNIVERSITY OF SOUTH AUSTRALIA SCHOOL OF BIOLOGICAL SCIENCES RESEARCH FELLOWSHIP IN BIOLOGY

Applications are invited from suitably qualified persons for a Research Fellowship tenable within any of the fields represented in the School of Biological Sciences of the University. The Research Fellowship, which is available from February 15, 1979, is tenable initially for one year but application may be made for an extension of up to a further twelve months. Applicants should have completed a Ph.D. degree prior to taking up the appointment, or have had equivalent research experience.

The appointment will be made according to qualifications and experience within the salary range \$A13,083 to \$A14,987. Persons with a Ph.D. will normally be appointed on the third step (\$A13,846). A contribution will be made towards the travel costs of the Fellow and his dependents in taking up the Fellowship.

The School of Biological Sciences is an integrated school, without subdivisions into separate departments. Research conducted in the school includes the following fields of study: Behavioural Biology (drug tolerance, neuro-transmitters and learning), Biochemistry (regulation of growth, carcinogenesis, cyclic nucleotides, control of DNA synthesis, chromatin substructure, cytokinins, phytochrome effects, aldosterone action, xenobiotic metabolism), Biophysics (energy conservation in photo-synthesis, fast movements in plants, solute transport by plant glands, vision physiology and anatomy), Developmental Biology (germ plasma in Anura, reproductive embryology, nuclear transplantation), Genetics (population genetics, radiation and chemical mutagenesis, genetics of Drosophila compound chromosomes, Drosophila development), Immunology (mechanisms of self-tolerance, and of autoimmune disease), Microbiology (control of viral macromolecular synthesis, viral pathogenesis, genetic control of recombination in Neurospora), Physiology (Animal) (locomotion, temperature and water homeostasis, responses of liver and abdominal nerve receptors to various stimuli, physiology and paleobiology of marsupials), Physiology (Plant) (structural and functional relationships between the plant embryo and surrounding tissues, drought hardiness), Plant cytogenetics (arid zone genetic systems, karyotype evolution, translocation heterozygosity), Population Biology (ecological and genetic studies), Vertebrate Palaeontology.

Applications, including full personal details, details of academic record and publications, a brief outline of research interests and names and addresses of at least two referees, should be lodged with The Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042, by October 31, 1978. Each applicant should ask his or her referees to forward their reports directly to the Registrar before the closing date.

Further details concerning the staff of the School and their fields of interest are obtainable from the Registrar. 7269(E)

ULSTER: THE NEW UNIVERSITY

SCHOOL OF BIOLOGICAL AND ENVIRONMENTAL STUDIES

The Development of a Biological System for the Treatment and Utilisation of Whiskey Distillery Waste

RESEARCH FELLOWSHIPS

Applications are invited for three fellowships tenable from January 1, 1979 to work on various aspects of this project which is financed by the Wolfson Foundation. Applicants should either be at the postdoctoral level or be graduates with at least several years postgraduate experience.

Ref: 78/106 *Microbiologist*—This appointment will be concerned with basic research and development of the microbial system employed for treatment of the waste and the production of single cell protein.

Ref: 78/107 *Chemical Engineer*—The responsibilities of this member of the team will cover the design, supervision of construction, commissioning and operation of a pilot plant continuous flow fermenter system at the distillery.

Ref: 18/108 *Fish Nutritionist*—The role of this appointment will be to examine the nutritional suitability, toxicity etc. of the single cell protein product particularly in relation to its use as a feedstuff for rainbow trout.

Salary scale: (with F.S.S.U./U.S.S.) £3,883 to £4,133 to £4,382 per annum, and the appointments will be for two years in the first instance with possible renewal for a further year.

Further particulars may be obtained from The Registrar, The New University of Ulster, Coleraine, Northern Ireland BT52 1SA (quoting appropriate reference number) to whom applications together with the names and addresses of three referees, should be sent not later than October 20, 1978. 7226(E)

THE UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF PHYSIOLOGY
RESEARCH FELLOW IN
EXPERIMENTAL
NEUROLOGY

Applications are invited for a Research Fellowship (in collaboration with Clinical Departments) to work on a five year M.R.C.-funded project involving the study of stretch reflex behaviour in human subjects, normal and abnormal, by the application of engineering methods to human limbs. The project is directed by Dr P. M. H. Rack from whom further information may be obtained.

Applications from medically qualified graduates will be particularly welcomed, although science graduates are also encouraged to apply.

Salary will be on the Research Scale 1A (£3,883 to £6,555 plus superannuation) according to age and experience. The appointment will date from January 1, 1979 or as soon thereafter as may be arranged.

Applications with curriculum vitae and the names of three referees should be sent to the Assistant Registrar, The Medical School, Birmingham B15 2TJ by November 21, 1978. Please quote reference RF/Phy/2C78. 7247(E)

UNIVERSITY OF
NOTTINGHAM
POSTDOCTORAL
RESEARCH FELLOWSHIP
IN IMMUNOLOGY

A POSTDOCTORAL RESEARCH FELLOW is required for an investigation of the interaction between immune complexes and macrophages in man, leading to the development of methods for assessing immunopathological situations. This M.R.C. supported post will run for three years, with a starting salary of up to £3,895 (Range 1A) and U.S.S. membership.

The immunology department has recently moved into new accommodation in University Hospital with excellent facilities for research. It is also involved in undergraduate and postgraduate teaching as well as the provision of a comprehensive clinical immunology service.

Candidates should have a working knowledge of immunological methods and an interest in the medical application of their work. All enquiries and requests for application forms should be addressed to Dr R. G. Q. Leslie or Dr W. G. Reeves, Department of Immunology, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH (telephone 0602-700111, extension 3510/3511). Closing date for application October 27, 1978. 7245(E)

UNIVERSITY OF
NOTTINGHAM
FACULTY OF
AGRICULTURAL SCIENCE
DEPARTMENT OF
PHYSIOLOGY AND
ENVIRONMENTAL STUDIES
RESEARCH FELLOWSHIPS
(PHYSICS/ENGINEERING)

Two fellowships are available for projects supported by the A.R.C. The first is concerned with the physics and economics of very low cost solar energy collectors for use in crop drying and the successful candidate will work with Dr J. A. Clark and Mr B. Wilton. The second project, supervised by Professor J. L. Monteith, will examine the feasibility of assessing the growth rate of crops from the spectral composition of reflected radiation, including measurements from the air.

Candidates should have a Ph.D. or equivalent experience in an appropriate branch of physics, engineering or environmental science. Both appointments are for 3 years on a salary scale commencing at £3,384 p.a.

Applications with the names of two referees should be submitted to and further details may be obtained from The Secretary, University of Nottingham School of Agriculture, Sutton Bonington, Nr. Loughborough. 7246(E)

UNIVERSITY OF GLASGOW
DEPARTMENT OF
BIOCHEMISTRY
POSTDOCTORAL
RESEARCH FELLOWSHIP

Applications are invited for the above post supported by a Cancer Research Campaign grant tenable for three years (maximum) from October 1, 1978, to work on cell interactions and intercellular communication in animal tissues. The project will investigate aspects of the structure and function of communicating junctions (gap junctions) formed between animal cells in culture and *in vivo*. Experience in developmental biology, electron microscopy or membrane protein chemistry is desirable. Starting salary in the range £3,883 to £4,382 (Range 1A of the Research and Analogous Staff scale). Further information may be obtained from Dr J. D. Pitts, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ. Applications, including a full curriculum vitae and the names of two referees, should be sent to Dr Pitts at the above address before October 20, 1978.

In reply please quote Ref. No. 4225(M). 7244(E)

LECTURES

NATO ADVANCED STUDY INSTITUTE
THE MECHANISM OF CONTINENTAL DRIFT
AND PLATE TECTONICS

at

Institute of Lunar and Planetary Sciences,
School of Physics, The University,
Newcastle upon Tyne, NE1 7RU, U.K.

March 27—April 10, 1979

An appraisal of the constraints placed on models for continental motions by geophysical and geological data.

Details by circular available November from:

Mr W. F. Mavor,
School of Physics,
The University,
Newcastle upon Tyne,
NE1 7RU, U.K.

MURDOCH UNIVERSITY
Perth, Western Australia

Murdoch University, Western Australia's second university, admitted its first students in February, 1975. The University is committed to taking a fresh approach to higher education, with the goal of responding directly to the conditions and needs of the late twentieth century. This is reflected in admission policies, organisational structures, programmes of study, philosophies of teaching and recruitment of staff.

The University is organised on a system of schools of study, with the Dean of each school having both academic and administrative responsibility.

Applications are invited from suitably qualified persons for the following position which is to be taken up on December 4, 1978 or as soon thereafter as possible.

SCHOOL OF MATHEMATICAL
AND PHYSICAL SCIENCES
(Dean: Dr L. R. Davidson)

POSTDOCTORAL
FELLOWSHIP—CHEMISTRY
(Ref. ENO353)

Applications are invited from suitably qualified chemists for a post-doctoral fellowship to investigate chemistry in non-aqueous solvents, in collaboration with Professor A. J. Parker. The research may be oriented towards applications of ionic solvation to hydrometallurgy, or solar cells, non-aqueous batteries and electrochemical science. However, chemists with a variety of backgrounds are encouraged to apply because a variety of basic techniques such as conductance, kinetics, polarography, calorimetry, potentiometry, spectroscopy and cyclic voltammetry are used in this type of work.

The appointment is for two years with the possibility of renewal for one further year.

Further details can be obtained from Professor A. J. Parker, Murdoch University, Murdoch, Western Australia 6153.

Salary Range: \$A13,083 to \$A14,987 per annum.

Conditions of Appointment include payment of a travelling allowance.

Applications. Two complete sets of detailed applications, quoting the appropriate reference number, including full personal particulars, details of tertiary qualifications, career history with description of posts held, area of special competence and interest, research completed or currently being undertaken. Membership of professional institutions or societies and positions of responsibility in these; list of relevant material published by the applicant, when available to take up appointment if offered and the names and addresses of two professional referees, should reach the Personnel Officer, Murdoch University, Murdoch, Western Australia 6153, by November 6, 1978. 7270(E)

STUDENTSHIPS

CITY OF LONDON
POLYTECHNIC
DEPARTMENT OF
BIOLOGICAL SCIENCES
S.R.C. (C.A.S.E.)
STUDENTSHIP

Applications are invited for a research studentship tenable for three years from January 1979 (or earlier, in the above department. We are seeking a physiologist/biochemist/pharmacologist who will join a small group studying the actions of Vitamin C on lipid metabolism in several vertebrates. Candidates should possess an upper second or first class honours degree.

Part of the research will be conducted at the J. A. Pyc Research Centre, Nr Stowmarket, Suffolk.

Further details of the research programme and application form may be obtained from Dr K. M. L. Morris, Department of Biological Sciences, City of London Polytechnic, Old Castle Street, London E1 7NT. 7268(F)

UNIVERSITY OF BATH
SCHOOL OF PHARMACY
AND PHARMACOLOGY
RESEARCH STUDENTSHIP

A recent graduate in Pharmacology or related discipline is needed to study arachidonic acid metabolism in human reproductive tissue. The project will be supervised by Dr K. I. Williams of the Pharmacology Group in co-operation with Mr D. Bamford, a consultant obstetrician at St Martins Hospital, Bath. The appointment, leading to a higher degree, will be for two years initially, current S.R.C. scales apply.

Applications with curriculum vitae and names and addresses of two referees to Dr K. I. Williams, Pharmacology, University of Bath, BATH BA2 7AY. 7223(F)

TENDERS

TENDER

East Sussex County Council
BRIGHTON POLYTECHNIC

Tenders are invited for the supply of a Rheometer of Advanced Design. Tender forms, returnable by October 6, 1978, and further details from The Chief Education Officer, P.O. Box 4 County Hall, Lewes BN7 1SG (Ref: SUPP/PGCT). 7271(T)

OUR GROWTH FACTORS BUILD STRONG CELLS MANY WAYS!

If you are having difficulty growing cells in Tissue Culture, our Growth Factors will help you. They increase survival times, accelerate growth rates and improve plating efficiency. In many instances, they also affect DNA, RNA and protein synthesis rates and a host of transport mechanisms. Collaborative Research Growth Factors now available from stock include:

Epidermal Growth Factor	(CR-EGF)
Fibroblast Growth Factor	(CR-FGF)
Multiplication Stimulating Activity	(CR-MSA)
Nerve Growth Factor	(CR-NGF)
Endothelial Cell Growth Supplement	(CR-ECGS)
Human Thrombin	(CR-HT)

In addition, we have [¹²⁵I] labelled derivatives and antisera for EGF, FGF, MSA and NGF.

To find out more about our Growth Factors and what they can mean to your research, call or write for our free technical bulletins. Or for immediate delivery of these products call our Order Department 617-899-1133.

The fast get faster.

Now the Ohaus Dial-O-Gram 1600 Series has a 10-gram dial; you can read to 0.1 gram directly, so every measurement is easier, faster.

We've also increased capacity to 2610 g with

three weights that are easily attached, and store conveniently in the contoured base.

We've kept the over-20 special advantages that make the Dial-O-Gram 1600's all best-sellers.

For example, a lever system to make these Ohaus balances

insensitive to out-of-level conditions. Or the patented Ohaus tare poise: it's internally threaded and contains a flat spring which allows you

to slide it along the beam for rough taring and rotate for fine adjustment.

If you'd like to find out how beautifully engineered a balance can be, write:
Ohaus Scale Corporation,

THE COMPLETE COLUMN

Everything you need to build a Column comes in a convenient storage box.

Decide what length you want to use, 35 or 65 or 95 cm.

Assemble it yourself in less than five minutes without tools.

Change the length whenever you need.

The same low cost for both 16 and 26 mm diameter.

Any one of three different column lengths is possible with each kit: 35, 65 or 95 cm. You can thus decide which of these best fits your personal needs, and easily assemble it, using the jacket sections provided, without tools.

Two flow adaptors included, to permit continuous variability of gel bed volume, and for precise sample application.

Improved flow characteristics are obtained through special center filter "dot" and flow spread pins.

Flow adaptor head designed for minimum dead space, both internally and externally.

Filters come ready-mounted on support rings, for a quick, snap-on attachment.

The adaptors are secured at the column ends by unique fork-type brackets, which assure the centering of the adaptors within the column. A fitting allows the hanging of a plumb line to determine the exact vertical orientation of the column.

New, clip-mount three-way valve, and sample applicator syringe, supplied with column.

Both 16 mm and 26 mm diameters available at the same low cost.

Optional accessories include a reservoir and column packing device, which will work with both available column diameters.

Order before December 31, and you will receive a free, 500 ml bottle of Ultrogel, in your choice of grade. Offer good while supply lasts!

nature Ocean sciences supplement

Reprints of this 40-page supplement covering many aspects of oceanography and the politics of ocean science, which appeared in the issue of 30th June, 1977, are now available at the following prices (including postage):

Single copy: UK 50p
Rest of World US \$1.00
Rest of World (Air) US \$1.50

10 or more copies: UK 35p each
Rest of World US 70¢ each
Rest of World (Air) US \$1.00 each

(Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd.)

To order please complete the coupon below, or write, enclosing the correct remittance.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if a is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

DOPAMINE

(Advances in
Biochemical Psychopharmacology, Vol. 19)

Edited by P. J. Roberts, G. N. Woodruff, and
L. L. Iversen

This book provides the most up-to-date information on the neurochemistry and pharmacology of dopamine, ranging from molecular mechanisms at the receptor to therapeutic approaches in disorders of brain dopamine metabolism.

429 pages, \$35.75 (1978)

NEURONAL PLASTICITY

Edited by C. W. Cotman

This volume presents a critical analysis of the ways in which neuronal circuitry adapts in response to internal perturbations such as lesions, and to external perturbations such as dramatically altered environments during development. It will be of value to the neuroscientist interested in the basic processes of neuronal plasticity, and to the clinician who recognizes the possible applications for nerve repair and recovery of function.

352 pages, \$32.50 (1978)

NEUROBIOLOGY OF THE MAUTHNER CELL

Edited by D. S. Faber and H. Korn

This book integrates all of the basic information known to date on this unique neuron. Major areas discussed are: morphology, synaptic topology, electrophysiology and pharmacology of the Mauthner cell, the macromolecular biology of its axon, the comparative biology of the sea lamprey neuron, and a critical review of developmental and behavioral studies utilizing this cell.

320 pages, \$32.50 (1978)

TRACER KINETIC METHODS IN MEDICAL PHYSIOLOGY

N. A. Lassen and W. Perl

This book provides a concise introduction to the mathematical treatment of tracers as used in medical and physiologic research. Emphasis is placed on noncompartmental ("black-box") analysis, but the compartmental approach is also presented and the formal similarities are noted. The material is essential for all research workers in physiology.

225 pages, \$28.60 (1979)

PHYSIOLOGY AND PATHOBIOLOGY OF AXONS

Edited by S. G. Waxman

This handsome volume presents the principles of structure and function of normal and pathological axons, and clinical correlates of laboratory findings. One-hundred-twelve detailed electron micrographs, and an extensive bibliography of more than 2000 current references make this compendium a valuable tool for students, neuroscientists, neurologists, neurosurgeons, and neuropathologists.

464 pages, 7 x 10 inches,
112 plates and 112 diagrams, \$42.25 (1978)

SENSORY PROCESSING, PERCEPTION, AND BEHAVIOR

R. B. Livingston

This monograph addresses itself to a central problem of human life, the problem of communication. It presents the main biological foundations for perception, judgment, and behavior, in an evolutionary and developmental context. In addition, it summarizes the evidence necessary for understanding normal and abnormal subjective experience and behavior.

112 pages, softcover, \$11.05 (1978)

ABNORMAL NEURONAL DISCHARGES

Edited by N. Chalazonitis and M. Boisson

This volume presents a comprehensive overview of the chemical and pathological modifications that trigger abnormal electrogenesis, and summarizes the current state of our understanding in terms of cellular and ionic mechanisms.

400 pages, \$41.60 (1978)

PATHOLOGY OF CEREBROSPINAL MICROCIRCULATION (Advances in Neurology, Volume 20)

Edited by J. Cervós-Navarro, E. Betz, G. Ebhardt,
R. Ferszt, and R. Willenweber

A survey of the basic principles and dynamics of cerebrospinal circulation, and the current results of research and clinical studies are presented in this multidisciplinary review. Extensive attention is given to specific pathological conditions.

628 pages, \$58.50 (1978)

KAINIC ACID AS A TOOL IN NEUROBIOLOGY

Edited by E. G. McGeer, J. W. Olney, and
P. L. McGeer

Kainic acid is the most powerful known substance that produces selective neuronal lesions in the central nervous system, while sparing axons of passage; it is also becoming the best studied of such substances. This volume aims to provide a broad review of the biology of this and related substances for investigators in a variety of neuroscience areas.

275 pages, \$29.90 (1978)

Europe should invest more in space science

SPACE science is expensive. NASA's science budget amounts to half-a-billion dollars a year. No individual European country could afford a national programme to satisfy the needs of its astrophysicists and geophysicists to do experiments in space, let alone provide opportunities for scientists working in other fields to realise the potential space has to offer. For Europeans, therefore, international collaboration is essential. It pools funds, expertise and ideas.

The European Space Agency (ESA) undertakes this task. If ESA did not exist, space scientists in individual European countries would have to rely on *ad hoc* international collaborations. More likely than not, most of these would involve NASA, which has a world lead in space science and can build spacecraft more cheaply and efficiently than any European country. Such collaborations could undoubtedly benefit all taking part: previous ones have proved this.

But total reliance on NASA could be dangerous. For example, some European scientists might want to build a mission which is of no interest to NASA at the time it is proposed. This might not be because it is unworthy of development but simply because it is not NASA's policy to build that type of mission at that time. European scientists need some independence and ESA should be able to provide it.

This is not to say that ESA itself should shun collaboration with NASA. On the contrary, wherever such collaboration is the best way of achieving the scientific aims of a particular project, it should be done. And this applies just as much to collaboration between individual countries and NASA.

If ESA is to provide European scientists with a certain amount of independence, it must provide them with enough launches. Many European scientists feel that, because of its appallingly low budget for science—about a tenth that of NASA—and poor value for money, ESA is failing them. And matters are unlikely to improve. The few funds which are available might well be spread even more thinly in future.

ESA is now under pressure to support missions to the planets. And it will soon have to decide how to pay for materials and sources, such as climatology.

Although it cannot support some of these scientific disciplines at the expense of the others, ESA must make sure that it does not lose the support of its best scientists. There is a danger that when a group of space scientists in Europe develops a world lead in its discipline, it will want to break away from ESA because ESA cannot give it the opportunities it needs to maintain that lead.

The key to ESA's future success is more space opportunities more often. This could be achieved if member states agreed to increase the mandatory science budget. Matters could be improved even further if ESA could cut costs.

ESA's Science Advisory Committee is arguing that some of the surplus money which will be available in the early 1980s—when the applications programmes start to cost less (see page 356)—should be diverted to science. But space science is not high on the list of priorities in most member states, who want an immediate financial return for their investments.

Good science, as always, has its intrinsic merit, but there are extrinsic reasons for a substantial investment in space science. In many industries, a strong programme of scientific research stimulates the development of new technologies. This applies *a fortiori* to the space industry. Building spacecraft for scientific research often calls for greater technological advances than building applications satellites. For example, ESA's faint object camera for the Space Telescope has put Europe's industry in the forefront of advanced photon detector technology.

Further, if the development and running of space applications is taken over from ESA by industry, as seems possible, further investment in space science will be the one in which national governments can keep space industries on their toes. Space science should not be seen as a luxury but as a necessary part of a healthy industrial development.

INSIDE: eight-page special on the European space science programme

0028-0836/78/10

Scientists press ESA to restore budget to 1971 levels

ESA's future is in the balance. The end of the decade set aside for developing space applications is in sight. At the end of this year, the ESA Council will have to make some fundamental decision on the future.

Exactly how scientists should influence that future was discussed last week at a meeting of ESA's Science Advisory Committee (SAC) in Nice. "Now is the time to say that science needs more support from the member states", is how Professor Klaus Pinkau, a member of the SAC summed up the conclusion of the meeting.

The SAC would like to see some of the funds now spent on applications diverted to science in the future. In 1971, ESA's science budget was cut to make room for the new space applications. Now that many of those applications are nearing the end of their development there is a strong case for

some of the money which will be released to be spent on science.

The other factor which distinguishes ESA's present predicament from the past is how to incorporate the 'new' fields of materials and life sciences and earth resources into the science programme. It is essential that the new fields should at least be screened for their scientific worthiness by ESA's scientific advisory bodies. If they are funded outside the mandatory science budget the situation could arise where a project in one of the 'new' fields would be funded, even though scientifically it was not as worthy as a geophysics or astrophysics experiment, simply because a separate budget had been set aside for it.

The West German government is likely to support the scientists' view. It has already said that it would like to divert funds from applications to

science. The French government, however, might need some hard persuasion from its scientists. And in the UK, diverting funds from industry to science is likely to produce many administrative difficulties because of the way it pays its ESA subscriptions.

The SAC will present its ideas to the Science Programme Committee (SPC) in November. At the end of the year, it will report to the ESA Council outlining its ideas for the future. □

What the critics say

EUROPEAN space scientists are far from content with the service they receive through the European Space Agency (ESA). According to Professor Martin Rees, who until last year was chairman of ESA's Science Advisory Committee, ESA's science budget is only about a tenth of NASA's. And many claim that ESA spends it inefficiently.

ESA was created in 1975 out of the European Space Research Organisation (ESRO) and the European Launcher Development Organisation (ELDO). The former had been solely responsible for space science: the latter for developing an independent launcher capacity for Europe. Since these two objectives have been under the umbrella of one agency, there have been fears that too much attention is being paid to the industrial programme (it takes 85% of ESA's budget) at the expense of science. According to one West German official "science developed a good reputation in ESRO, but ESA is not taking enough care of it". In 1971 ESRO defined a 'minimum viable budget' which amounted to only two-thirds of its expenditure, and ESA has kept it since.

The scientists' dissatisfaction is fuelled by the frustration of some ESA's staff who feel that ESA is responsible for many ills for which it cannot be held entirely responsible. They see the exceedingly difficult task of

trying to implement a European science programme within the constraints of a very limited budget (about £50m per year, compared to CERN's £190m for high energy physics). And in recent years the reduction in many national programmes has put an even greater burden on that budget.

So far all ESA's scientific missions have been paid for out of the mandatory science budget. Each of the 11 member states (Belgium, Denmark, France, Germany, Ireland, Italy, the Netherlands, Spain, Sweden, Switzerland, and the UK) contributes to the mandatory budget in proportion to its gross national product up to a maximum of 25%.

But as time goes on, European space scientists need larger space missions more often because they need to build on the previous research of European and national missions. On top of that, scientists in fields which have never been catered for by a European space mission, in particular planetary science and climatology, are putting pressure on ESA to provide them with opportunities. And looking further to the future materials and life scientists might well be applying similar pressure if they gain their entrée into space through the launch of a manned laboratory—Spacelab in 1983. According to one West German scientist "a multiplicity of disciplines are now knocking on the mandatory science budget's door".

The difficult position ESA is in is illustrated in the long term planning

reports produced by its astronomy and solar systems working groups in 1976. They both concluded that a basic programme in each of their respective fields over the next ten years would take up the entire mandatory budget available over that time.

It is also claimed that ESA is inefficient. In recent evidence to the Committee on Science and Technology, US House of Representatives, Dr Wolfgang Finke, speaking in his capacity as Head of Space and Transportation of the Bundesministerium für Forschung und Technologie (BMFT), said that a conservative estimate of the cost of an international project "is more or less equal to the product of the 'true' costs of the project done nationally and the square root of the number of participating countries". For ESA with eleven member states this rule implies very expensive projects indeed. However, a direct comparison of the costs of ESA's satellites and NASA's or those built in an individual country, is very difficult because of differences in accounting and charging overheads. Nevertheless ESA is in the process of making such a comparison.

A major factor contributing to high costs is ESA's industrial policy. The policy was created to help develop the European aerospace industry and states that industrial contracts have to be distributed throughout member states in proportion to the size of their contributions to ESA's subscription. Thus an ESA satellite may be built in

Report was compiled
by Redfearn

several firms in several member states. There is little or no competition for contracts and therefore little natural price control. Also because space contracts are few and far between, and are only small fry to the aerospace industry, they suffer from lack of continuity and standardisation.

Standardisation could only be introduced if ESA built a series of similar satellites. However, it is unlikely that enough satellites could be built with the available funds to make standardisation a reality. In the early days, ESRO attempted to build a standard bus, but after the first, TDI, a uv satellite launched in 1972, it had to scrap the idea. "European missions have never been suitable for a standard bus" says Mr Roy Gibson, ESA's Director-General. Nevertheless, Dr Edgar Page, Head of the Space Science Department at ESA's technology centre, (ESTEC), in Noordwijk the Netherlands, believes that ESA's future success will depend to a large extent on whether or not it can achieve some sort of standardisation. At the moment, ESTEC engineers are looking at standard subsystems rather than standard buses, but these are more likely to find uses in applications satellites rather than scientific ones.

Reusing spacecraft might be another way of cutting costs. At the moment NASA's Space Shuttle is the only vehicle capable of retrieving or refurbishing spacecraft in orbit, so the cost-effectiveness of doing this will be very dependent on its launch costs and precisely how it is used. So far ESA is participating in two future reusable missions: Spacelab and NASA's Space Telescope. Spacelab, however, will probably be very expensive to operate, one of the reasons being the high cost of using the Shuttle. NASA is quoting \$31m for a Space Shuttle launch by non-US government users.

Some of the missions ESA has already flown and many of the ones it is considering for the future are too large and expensive for any individual country to build. Mr Ernst Trendelenburg, ESA's Director of Scientific Programmes, believes that these are precisely the kind of missions ESA should be adopting. Mr Gibson, however, believes that ESA should also provide smaller facilities. These differing views are reflected in the scientific community itself. Largely, big launches mean high energy astronomy, and a rather small community of users, and small launches mean geophysics and more users, except for certain very sophisticated experiments.

Until 1972, scientists needing small payloads carrying experiments of short duration were catered for by ESA's sounding rocket programme. This was stopped, however, on the grounds that

sounding rockets are within the scope of national programmes. Now ESA only helps out in the running of ESRANGE, a rocket range in Sweden. The main hope for the future in catering for small payloads is Spacelab. But there are fears that it might be too expensive to be used to best effect. "We had hoped Spacelab would be a seven day balloon or rocket facility", commented one German scientist "but it looks like becoming a seven day satellite facility". And for atmospheric scientists, at least, it will not be as useful as sounding rockets because it pollutes its environment and its orbit is uninteresting to them scientifically.

ESA's scientific satellites have become more complex as time has passed. In astrophysics, for example, early satellites such as TDI were designed to survey the sky at various wavelengths and identify interesting objects. Follow-up satellites need to observe those objects with greater pointing accuracy and higher resolution. Large

observatories in space are needed to do this. The instruments for them often have to be built under the direction of ESTEC because they are beyond the technological capabilities of universities and research institutes. Many scientists feel that this trend is taking away their opportunities to design and build instruments which are just as important for maintaining a strong scientific community as being able to do theoretical work from satellite data. ESA is developing a will of its own.

One possibility for overcoming this problem is to build large observatories within consortia of institutes. Professor R. Lust of the Max Planck Society in Munich and the first scientific director of ESRO, believes that this is possible. "EXOSAT (ESA's X-ray satellite to be launched in 1981 on Ariane) is a large observatory satellite and it is being built in industry under the direction of ESTEC. Cos B (ESA's cosmic ray satellite launched in 1975) was just as complicated and it was

built successfully in five different institutes".

Not all scientists are so critical of ESA. In spite of its shortcomings some think it provides an essential service. Professor van de Hulst of Leiden University, the Netherlands, for example believes that "ESA suffers from the problems of a big international organisation but it must be judged on the projects it has done. These have been good." And Professor Roger Bonnet, of the Laboratoire de Physique Stellaire et Planetaire, near Paris and chairman of the SAC thinks that it offers a certain independence for Europe. "Cooperation with NASA can be difficult", he says "because NASA won't always be willing to adapt its programmes."

Inevitably, the least discontented scientists are those in countries with an active national programme. Holland, for example, has a small but world-renowned astrophysics community which has been able to take advantage of opportunities on some ESA satellites, such as Cos B, and on other satellites in collaboration with other countries such as the NASA-Dutch X-ray satellite ANS-1 and the NASA-Dutch-UK infrared satellite, IRAS due for launch in 1981. It is just beginning to consider what kind of satellite to build after IRAS. Two possibilities are an X-ray satellite and another IR satellite.

Perhaps the country where ESA's problems are posed most acutely is the UK. Unlike most other European countries, its contributions are paid by two agencies out of two separate budgets. The Science Research Council (SRC), which pays about £8m, is responsible for science and the Department of Industry, which pays about £30m, for applications. The SRC therefore is a focus for scientific opinion within the UK government. In 1975, during a period of financial stringency, the SRC adopted the policy of squeezing funds for big science. Before then the UK's national space programme exceeded its contribution to ESA. Now it is slightly less and current national programme will to an end next year after the of UK-6, an X-ray satellite, some £9m. Apart from satellite, to which the UK a small contribution, the other approved international organisation outside ESA ing rocket programme to the bare bones the SRC is contributing for money it.

It is the community which is left out. In the end, the money is spent by ESRO and

further opportunities to help them maintain the world lead they gained after UK-5, an X-ray satellite launched in 1975. They feel that the data from EXOSAT, ESA's large X-ray observatory, will be spread on the ground too thinly to be of much use to them. "The future of British astrophysics does not lie with ESA" commented one British high energy astronomer.

Recently the SRC has been devoting some thought to ways of providing UK scientists with more space opportunities and of cutting the cost of space science. It is considering collaborating with NASA on a multi-disciplinary refurbishable satellite (MRS) to be launched and refurbished by NASA's Space Shuttle. The idea is to increase the lifetime and usefulness of a single satellite by repairing it and altering its payload either in orbit or on the ground. The SRC hopes that an MRS could be a very cheap way of doing both astrophysics and geophysics experiments. There are some fears, however, especially among geophysicists that by trying to please everyone it will please no one.

The SRC would like to involve ESA in studies on the MRS, but enthusiasm for the idea within ESA is low. There are doubts about its feasibility and worries that it would mean yet another collaboration with NASA. Nevertheless, ESA will at least be obliged to look into the idea although it could not be studied in time for ESA's next project decision at the end of 1979.

West Germany's policy is to conduct as much of its space science through ESA as possible and it would actually like to increase its contribution to ESA's mandatory science budget. However, it could only do this if all member states agreed to increase their contributions accordingly. In the long term, Germany would like to see funds diverted to science from applications. "Applications should only go on in ESA for a short time," says Dr H. Strub of the BMFT, "then they must be marketed and taken out of ESA's control. In science ESA runs and develops satellites but in applications, the users must take this over once the technology has got off the ground". In particular, Germany would like to see more spent on science when ESA's own launcher, Ariane, and Spacelab near the end of the most expensive phases of their development. By the mid-1980s, it would like ESA's entire budget to level off at 350 mau (about £230m) at today's prices (it is now about 530 mau, £345m) and most of it to be spent on science and new fields to be explored on applications and instruments such as remote sensing and geophysics.

The greatest pressure on ESA to do more space science comes from

Germany. German scientists would like to consolidate the experience they gained from the Helios probes, two solar physics missions launched in 1974 and 1976 in collaboration with NASA. The French would also like to build on their collaborations with the Soviet Union on a number of planetary missions. Germany is also considering collaborating with NASA on Robi, a cheap X-ray satellite.

Scientists within the SAC feel many of ESA's problems could be solved if member states agreed to increase the mandatory science budget and ESA could increase its cost-effectiveness. Professor Klaus Pinkau of the Max Planck Institute für Extraterrestrische Physik recently sent out a questionnaire to European space scientists canvassing opinion on ESA. "The science budget doesn't need a six-fold increase" Professor Pinkau told *Nature*. "This would be out of proportion to the funding of the rest of science". He would like to see the mandatory science budget restored to its pre-1971 level, about 100 mau (£65m) at today's prices, and would like ESA to make efforts to increase its cost-effectiveness by at least 20%. Over a ten year period, he says, ESA

should be able to fly one mission a year if it built five missions costing 50 mau each, four costing 120 mau and one very good and expensive one costing 250 mau.

To achieve this, however, ESA would have to make special efforts to keep the cost of small satellites within the 50 mau limit. Professor Pinkau suggests that facilities on the ground could be used more efficiently so that the science budget does not have to pay for facilities which are not being used for some part of the year. "Good management should show where you lose money", he says. The industrial policy might also have to be revised so that the principle of fair return would apply over say ten years.

This scheme, he feels could incorporate materials and life sciences into the mandatory budget. Earth resources would have to remain outside the budget but could still be refereed within the procedure of the SAC. Such a scheme however is dependent on the member states agreeing to increase the science budget and on ESA achieving a substantial reduction in costs. The former lies within the power of national governments. The latter is up to ESA. □

The multi-discipline refurbishable satellite

THE MRS is one country's (the UK's) attempt to find more flying time outside the auspices of ESA. Under consideration by the Astronomy, Space and Radio Board of the Science Research Council, it would use The Godard Space Flight Center's kit-form Multi-mission Modular Spacecraft (MMS) as a base (see figure) and erect on it instruments to serve both astronomers and geophysicists. A study is underway (it will report in January) at British Aerospace, Stevenage, to assess the difficulties of combining the instruments on the same vehicle. "And it doesn't make life easy" said one scientist.

The MRS would be a collaboration with NASA, which is interested in flying high energy astronomy experiments. But NASA is not concerned with flying geophysics on this mission; so geophysicists in the UK are suspicious that the exercise is one designed by high energy astronomers to 'sell' the project to the Science Research Council, which is conscious of the need to serve as many scientists as possible.

Funds would be needed by about the end of 1980, for a launch from the Space Shuttle in 1985. The UK would assemble the satellite, at a cost of £15-£20m—twice the cost of UK6, for example. But the MRS could take a payload of up to 1,000 kg, and could

Exploded view of MMS basic modules and elements

have a continuous data rate an order of magnitude greater than UK6.

Atmospheric physics may be the casualty of the multidiscipline confrontation, as its requirements are least compatible with astronomy. But the MRS is retrievable and refurbishable and is designed to make use of the supposed reduced costs of reuse of the MMS base and some instrumentation. Geophysics could get a better look in on a subsequent launch.

But everything depends on whether an agreement can be reached with NASA on the first and subsequent flights—as always with such collaborations—and, ultimately, on the uncertain cost of operations with the shuttle. □

THE ORGANISATION

Roy
Gibson
ESA's
Director-
General

Who makes the decisions?

FINAL approval for ESA's scientific projects is granted by the Science Programme Committee (SPC), the body responsible to the ESA Council for running the science programme within the financial limits set by the Council. Each member state is represented on the SPC by its own delegates and is allowed one vote in any decision.

Projects for final selection are put to the SPC by the Director-General, Mr Roy Gibson. He is advised by the Science Advisory Committee (SAC) and four working groups: the astronomy working group (AWG), the solar system working group (SSWG), the materials sciences working group (MSWG) and the life sciences working group (LSWG). Experts appointed by the Director-General and acting in their own personal capacity, sit on each advisory body. The MSWG and LSWG were recently created. The two areas of science they serve are new to ESA. One life scientist, one meteorologist and four representatives of the astrophysical and geophysical sciences sit on

the SAC. Its meetings are attended by the chairmen of the working groups.

The executive recommends that new project proposals are screened by the working groups. The money spent on early studies is authorised by the Director-General.

If preliminary studies are successful, the Director-General may recommend that a project be considered by the SPC. The SPC will then decide whether or not to go ahead. When a project has been approved, ESA puts out a call for proposals for experiments.

Although there is no formal link between the working groups and the SAC, in practice they work together quite closely. Typically, out of 10-20 project proposals put before the working groups, 5-6 will be passed on to the SAC and three on to the SPC. On average the SPC chooses one major project for development every one and a half to two years.

So far, the SPC has only approved one experiment in the materials and life sciences, the Sled for Spacelab, to be funded out of the mandatory science budget. The rest of the experiments approved in these disciplines are for the first Spacelab payload and are being paid for in individual countries and out of the Spacelab budget.

As well as vetting individual project proposals, the working groups and the SAC discuss overall policy for the science programme. In 1976, for example, the AWG and SSWG both produced reports on the science and projects needed in their respective fields up to 1990. About once every four years, the SAC also discusses plans for the future, such as it did last week.

Responsibility for seeing that the science programme is put into practice

rests with Mr Ernst Trendelenburg, Director of Scientific Programmes. His responsibility now includes future science programmes. To speed up decision-making, he would like to see the number of early studies cut, especially those for projects which are obviously unsuitable for further development from the outset. □

Four steps to get a project off the ground

A SCIENTIFIC mission proposal which has been studied by the relevant working group and found scientifically worthy will go through four 'stages' before it is finally approved and the spacecraft is built. Each stage is independent of the others so that the mission can be scrapped at the end of any one without breaking contracts or jeopardising the money which would be spent in the subsequent stages. Most projects which go beyond phase A, however, are completed. The steps in a mission's development are as follows:

Mission definition or assessment. This is a study stage to define the mission and its payload. It is done under the direction of ESA by seven to ten scientific experts in the mission's field of study. They measure the interest shown in the mission by the scientific community in Europe, assess its scientific soundness and the ability of European universities and institutes to build instruments capable of achieving its scientific objectives. They also predict what sort of system will evolve, how

● turn to next page

The cost: where the money comes from, where it goes

ESA's TOTAL budget for 1978 is about 530 mau (one mau is roughly US \$1.3 million). Of this, 75.5 mau is to be spent on the science programme, about 80 mau on the general budget and the rest on Spacelab, Earthnet and applications programmes such as telecommunications satellites, Meteosat and the development of ESA's own launcher, Ariane.

The science budget and part of the general budget are mandatory. Each member state contributes to them in proportion to its gross national product. Thus, in 1976, Belgium contributed 3.48%, Denmark 2.26%, France 21.20%, Germany 25.25%, Italy 13.23%, the Netherlands 5.34%, Spain 4.44%, Sweden 4.46%, Switzerland 3.56% and the United Kingdom 16.47%. So far all ESA's scientific missions have been conducted through the mandatory programme, even

though, in principle, nothing excludes a group of interested member states from funding an optional one.

The mandatory part of the general budget funds 'basic activities' such as the technological research programme at ESTEC, the salaries of some headquarter's staff, the documentation centre at Frascati and the infrastructure. In 1978 it amounted to about 54 mau. The rest of the general budget is for facilities which cannot be charged to any particular programme such as the cost of buying the agency's headquarters in Paris and the cost of running the Ariane's launch pad at Kouru in French Guiana.

All of the science budget is spent on building spacecraft and very large instruments such as those for Spacelab or large observatory-type free-flyers, and on maintaining facilities for tracking them and receiving data. Most of

the experiments on board satellites, however, are built in universities and institutes and are funded out of national funds for scientific research.

In 1971 the mandatory science budget was fixed at 28 mau. In 1978 that level is 75.5 mau and in 1979 it is expected to be about 79 mau. As scientific satellites cost between 50-100 mau, and some of them even more, this level of funding means that ESA can build one every one and a half to two years.

The capital cost of launches is not the only expense, and already the science budget is almost fully accounted for until the end of 1980. It is proving difficult to find the 2 mau needed to keep Cos B, ESA's cosmic ray satellite launched in 1975, operating for another year. This sum has not already been included in next year's budget because Cos B has exceeded its expected lifetime. □

much it will cost and what sort of effort in terms of manpower and technological research will be needed. The study normally takes three months.

Phase A or study stage. Those proposals not thrown out after the assessment stage are subjected to a more detailed definition. This is usually done under the direction of a technical study team which may contract out to industry some parts of the study. It involves a detailed estimate of the cost and time to completion and a thorough description of the payload, spacecraft, orbit, ground support and data handling and analysis. Typically the study stage lasts nine months and costs 1% of the final project cost.

Phase B or design stage. A scientific project which enters this stage has usually been approved for development by the SPC. It is put under the management of a project team which will be responsible for it until it has been launched and is operating. The project team places contracts in industry for the design of the spacecraft. Typically, phase B takes one year and costs 10% of the final cost of the project.

Phase C/D or development and production. Typically, for a scientific satellite, this will take three years and cost 40–70 mau.

The project teams include engineers from ESTEC's department of development and technology (DDT). When they are not part of a project team they do research in one of the DDT's divisions on various aspects of advanced space technology. This research is important for keeping Europe in the forefront of space technology.

Before launch all ESA satellites are tested at ESTEC. It has the only facility in Europe—a high vacuum chamber 14 m high and 10 m in diameter—large enough to test a satellite with its booms deployed or the nose cone of Ariane. Once the satellite is in orbit, however, operational responsibility for it shifts to the European Space Operations Centre (ESOC) at Darmstadt, West Germany. As well as control of the orbit, ESOC is responsible for setting up ground stations to receive data.

One of ESA's objectives is to encourage development of European industry. This is reflected in the way it puts out tenders to industry for its scientific satellites. Its industrial policy states that each member state should receive the same percentage of the total contract put out to tender as it contributes to the mandatory science budget. This is irrespective of whether it is participating in the scientific payload. This policy is controlled by the Industrial Policy Committee (IPC) which can suggest how contracts should be placed to ensure that each country gets a fair return. □

ESA's SCIENTIFIC RECORD

The past . . .

ESA and its predecessor ESRO have launched twelve scientific satellites since the first launch in May 1968. Six of them are still operating: Cos B, a highly successful gamma ray observatory launched in April 1975; Geos 1, which failed to reach geostationary orbit in April 1977 but is producing some useful magnetospheric data; ISEE-2, which was launched in October 1977 and is observing the interaction of the solar wind and the Earth's magnetosphere in conjunction with NASA's ISEE-1; Meteosat, launched in November 1977, contributing to the Global Atmospheric Research Programme and the World Weather Watch; International Ultraviolet Explorer, the ultraviolet astronomical observatory, launched as a NASA-UK-ESA collaboration in January 1978; and Geos 2, a 'copy' of Geos 1, successfully launched into geostationary orbit in June 1978 to observe the magnetosphere.

Of the previous seven satellites, five were designed for magnetospheric and atmospheric experiments, and two for high energy astronomy: ESRO-II for cosmic rays and solar X-rays, launched May 1968) and TD-1 (a UV satellite launched March 1972 and operational for two years but troubled by malfunctioning tape recorders). Of the complete list of thirteen satellites, nine were for Earth-related observations (mostly on Sun-Earth interaction) and four for astronomy. Astronomical satellites were launched in 1968, 1972, 1975 and 1978.

The present . . .

ESA's report to the 21st COSPAR meeting in June 1978 says that while Sun-Earth relationships "continue to be an important feature of the agency's scientific programme", there is a change afoot: "an increased emphasis is being placed on astronomical studies". This is reflected to some extent in the current list of approvals (four main projects, two of which are astronomical), and to a greater extent among the competing proposals for the next project (three out of five are for astronomy). Approved are:

The first Spacelab payload. Spacelab is scheduled to fly with the tenth flight of the Space Shuttle on 3 December 1983. It will be manned, but will stay aloft for only 7–30 days. According to ESA's 1978 report to COSPAR "the composition of a typical Spacelab payload will be distinctly different from

that of a conventional research satellite". Life sciences and materials sciences will benefit from 'look-see' experiments in a new environment. But the observing time is too short for much astronomy.

EXOSAT. This 0.1 keV to 50 keV X-ray astronomy satellite is scheduled for launch on Ariane in February or March 1981 (or by Thor-Delta if Ariane is not ready). It has two operating modes: occultation, using the Earth or Moon to determine the position and structure of X-ray sources, and arbitrary pointing, which will be used to determine this spectral and temporal variation.

Out of Ecliptic/Solar Polar Mission.

This is a joint mission with NASA to launch two spacecraft in February 1983, to fly out of the plane of planetary orbits and around the North and South poles of the Sun. The gravitational field of Jupiter will be used to swing the spacecraft out of the ecliptic. The objective is to extend into three dimensions our knowledge of the solar corona, the solar wind, the solar magnetic field, the cosmic ray flux, and interplanetary/interstellar neutral gas and dust.

The space telescope. This, as ESA's latest report to COSPAR says, "is the most ambitious project in space astronomy currently planned and will dominate astronomical research for the rest of the century". ESA is participating at a level that will allow Europe's astronomers just 15% of the observing time on the high-resolution, 2.4 metre telescope. The telescope should be launched from the space shuttle at the end of 1983 with five separate focal plane instruments. In a 500-km high orbit, it will be retrievable and refurbishable, and should serve astronomers for two decades.

The future . . .

THE European Space Research and Technology Centre (ESTEC) in the Netherlands is investigating the scientific and technical merit of several spacecraft which will compete for selection as the scientific project to follow the ESA/NASA space telescope which is due for launch in 1983.

To effectively use the science budget ESA's Science Policy Committee (SPC) will have to decide on which experiment to launch by the beginning of 1980. The next mission should then be ready for launch in 1985.

The options are already known. According to Dr D. E. Page, head of the science department at ESTEC, any new mission proposals could not be studied in time for next year's decision

Already approved: space telescope, to be launched from the NASA shuttle, and the Out-of-Ecliptic mission, both scheduled for 1983.

because available staff at ESTEC are already committed. The selection will, therefore, be from the following:

Extreme ultraviolet and X-ray survey satellite (EXUV). The proposal for this satellite stemmed from observations made in 1975 by NASA's X-ray satellite, Copernicus. Before that it had been thought that extreme UV radiation was too heavily absorbed by the interstellar medium (ISM) to be observed. Copernicus, however, showed that the local ISM is thinner than had been expected and that in certain directions the emissions can be observed from objects up to 100 parsec away.

ESA's EXUV satellite would survey the sky in the waveband 15 Å–1,000 Å with a few arc min resolution. It would provide information on very hot stars, which emit most of their radiation in the EUV waveband (250 Å–1,000 Å), and stellar coronae. It would also help study the origins of the diffuse XUV (15 Å–250 Å) background.

The estimated cost on completion of an EXUV satellite is 75 mau. This includes half an Ariane launch.

Astrometry satellite. The position of stellar objects can be measured with far greater precision from space than from Earth. In principle, positional accuracy could be improved by a factor of 20 and the number of observable stars could rise by a factor of 10 to 100.

The idea for an astrometry satellite in ESA is about nine years old. However, it has never been one of the candidates for final selection because previous studies have been abandoned at the mission definition stage. One of the problems is that it could be technically very demanding to achieve the claimed increases in accuracy. Because of this, an astrometry satellite could be expensive, of the order of 95 mau.

Grazing-incidence solar telescope (GRIST). This would be an ESA-funded Spacelab facility to observe the Sun in the soft X-ray and UV wavebands (100 Å–1,700 Å). The advantage of using Spacelab (rather than flying GRIST separately) is that the telescope could be flown as one of several solar telescopes, making simultaneous obser-

vations in a variety of wavelengths. NASA is considering building the other telescopes.

The option of another large Spacelab facility, the large infrared telescope (LIRTS), has recently been shelved on cost grounds. Interest in focal plane instrumentation for LIRTS, however, is still being maintained at ESTEC in case the project is ever reconsidered as a free-flyer. The major disadvantage of putting a heavy instrument on Spacelab is that the launch cost for a 7–30 day flight is as much as the cost of launching it as a free-flyer with an observing time of several years.

Sun-Earth observatory and climatology satellite (SEOCs). This would measure the Earth's radiation budget more accurately than previous NASA satellites. It would help investigate the physical processes controlling the budget by monitoring spatial and spectral changes in the incoming and outgoing radiation. In particular it would monitor the incoming solar UV flux in conjunction with the composition of the stratosphere and observe interactions between different atmospheric levels and the Earth's surface.

SEOCs would be put into circular orbit at a height of 1,150 km and 57.5° inclination. It would only be able to improve on existing measurements if it were to interact with geostationary satellites, such as Meteostat, to obtain information on the diurnal characteristics of the atmosphere. It would also have to interact with polar orbiting spacecraft if it were to study the complete radiation budget. Because the usefulness of SEOCs would depend so heavily on it interacting with other spacecraft, ESA is looking at the possibility of building two.

The cost on completion of one satellite plus the cost of half an Ariane launch is estimated to be at least 85 mau. However, ESA has not yet decided whether to fund climatology out of the mandatory science budget or as an optional applications programme. So SEOCs could be removed from the list of candidates for the next scientific mission and be funded separately.

Polar orbiting lunar observatory (POLO). In spite of NASA's Apollo and Lunar missions, there are still fundamental questions about the Moon left unanswered: for example does it have a core, what is its internal temperature, what is its thermal history, and what was the origin of the magnetic field of the early Moon? Some scientists feel these questions would be better answered with the aid of an orbiting spacecraft than a lander, such as Apollo, which is necessarily very limited in the area it can observe.

A study is currently being rushed through at ESTEC to look at the possibility of building POLO very cheaply from Geos 3 hardware and launching it on the fourth Ariane test flight at the end of 1980. This would mean that POLO could be built cheaply and quickly. It might even mean that it could be funded in addition to one of the other options. The possibility of this happening, however, has grown more remote as cost estimates have risen from a few mau to well above 10 mau.

The SAC will not have to decide which project should follow the one to be approved at the end of next year until the end of 1980. ESA, however, will be sending out a call for mission proposals for that decision in the middle of next month. No one yet knows what that will bring but there is growing pressure from planetary scientists in Europe for ESA to launch spacecraft out of Earth orbit to other parts of the solar system. And POLO is not the only idea they have for the future. They are also considering a cometary mission and a mission to the asteroids. At a workshop organised by ESA earlier this year, European scientists came out in favour of a dual mission to comets Halley and Tempel 2. The proposal they agreed on was to fly-by Halley's comet during its next nearest approach to Earth in 1986 and then, following an Earth swing-by, to rendezvous with Tempel 2 in 1988. Both the proposed cometary and asteroid missions would be extremely expensive. The cost for the cometary mission might be about 500 mau. □

Astronomy in the 1980s

Astrophysics and geophysics are ESA's two oldest disciplines. Professor A. P. Willmore, of the University of Birmingham's Space Research Department presents the case for launching sophisticated equipment to do high energy astronomy . . .

EVEN more than for most sciences, the last two decades in astronomy have been a period of rapid technological development for all its branches. The substitution of high quantum-efficiency detectors for the photographic plate in optical telescopes, the application of large aperture synthesis telescopes in radio astronomy and the entire histories of infra-red, ultra-violet, X-ray and γ -ray astronomy are contained within the last 20 years. The application of space-flight to astronomy, on which the possibility of the newest branches of astronomy (only excluding work in the infra-red) has depended and which promises some important advances in the older branches too, has also occurred during this time.

The last two decades have also been a quite exceptional period of discovery whose many results now demand exploitation. It is also most unlikely that the phases of technological development and discovery are yet at an end. Thus charting a course for astronomy, especially space astronomy which is so costly, will require careful selection from a broad spectrum of projects, any of which in less exciting times might have seemed suitable to be pursued.

Space astronomy—for the obvious reason again of its expense—is highly internationalised; most experiments or facilities involving international teams with members from both sides of the Atlantic. The degree of internationalisation exceeds that even in nuclear physics so that a distinctively European programme is hard to conceive and it is useful only on a world scale to identify the promising paths to develop. But several branches of astronomy are alive and well in Europe, particularly in the UK, and there is no reason to doubt that UK astronomers will be well represented in world class astronomy, provided of course that funding at a minimum necessary level is available.

The sensitivity of large optical telescopes has been substantially enhanced in recent years by the development of photo-electric detectors whose quantum efficiency is far higher than that of photographic plates and whose performance in other respects is comparable. However, the ability of a telescope to detect and resolve objects which are very distant and therefore faint and of small angular diameter depends also on its effective image quality and on the brightness of the night sky. The angular resolution of any good, large optical telescope is determined not by diffraction or the quality of its construction but by the atmosphere, and consequently the Space Telescope, a 2.4m. orbiting telescope being built by NASA with ESA as a minor partner, will have an effective resolution 10 times and a sensitivity 100 times that of the large ground-based telescopes.

The Space Telescope can operate over a wide wavelength range, and will be an ideal instrument for the study of the most distant galaxies which are of course those which are observed in the earliest epochs in the Universe, closest to the time of the Big Bang, and around the epoch of galaxy formation. The measurements of the motions and parallaxes (the apparent motions due to the Earth's orbital motion about the Sun, on which ultimately all astronomical distance scales depend) and of astronomical objects are severely limited by atmospheric effects, and either with the Space Telescope or with satellites constructed for the purpose, improvements of about an order of magnitude should be attainable.

The short history of X-ray astronomy is especially remark-

able for the profusion of new discoveries, for example the close binary sources containing compact stars such as neutron stars and—one supposes—black holes, which allow properties—the mass, at least—of the compact star to be determined in a number of cases. It is salutary to recognise the relative crudity of the techniques which have generally been employed in making these observations, which are about equivalent to carrying out optical astronomy with something between a photographic light meter and a box camera. But much technique development has been carried out in the last 10 years, and the new techniques are now ready to be exploited. Later this year the NASA HEAO-B satellite should be launched with a medium size grazing incidence telescope. This will have an angular resolution roughly two orders higher than any previous X-ray instrument, comparable for the first time with that of an optical telescope. The sensitivity too will be far higher than that of any previous instrument—indeed it will be much better than that of any present X-ray sky survey, which will undoubtedly prove some limitation on its use. This telescope is likely to be able to detect the X-ray emission from clusters of galaxies at distances approaching those of the most distant quasars, thus providing another means of observing the early Universe. Other means of imaging at higher X-ray energies have also been developed, and this is a whole field that is sure to prove productive.

Recent observations of X-ray spectra, which like the spectra of radio sources are dominated by continuum emission, have shown the presence of measurable line emission in a wide variety of sources. This generally arises from highly ionised atoms, usually of Fe, which are present in the source, which must be at a high temperature since it is an X-ray emitter. A high energy feature, however, is believed to be cyclotron emission from around a neutron star, thus allowing for the first time a direct measurement of the large magnetic field (about 10^8 T) around these objects. The diagnostic value of such detailed spectrum observations is very high and together with much improved observations of the spatial structure of sources this is bound to prove an area of important development.

X-ray observations are generally considered to extend up to the electron-positron annihilation radiation at 512 keV. Observations of the γ -ray sky at higher energies are relatively scanty, depending on the surveys carried out with spark chambers on the SAS-2 and Cos-B satellites. Whilst X-ray and optical objects such as the Crab nebula and the Vela pulsar are detected at γ -ray energies, there is a good chance that the typical γ -ray source will prove to be qualitatively different from those observed at lower energies and promising new observational techniques such as drift chambers and double Compton scatter telescopes are now in existence.

In selecting the projects of the future, the obvious criteria to use (and one implicitly accepted in the examples already cited) will be the extent to which they are likely to contribute to fundamental topics—either cosmology, or fundamental physics as general relativity or the properties of nuclear matter. But throughout high energy astronomy, better surveys will be vitally important in the next decade, and will surely bring to light many new types of astronomical object. It will be worth remembering that even at lower energies, both pulsars and quasars were discovered within the last 20 years or so. □

Science in the solar system

... and Dr Alan Johnstone, of the Mullard Space Science Laboratories, poses some of still-unanswered questions about the solar system.

WITHIN the consultative structure of both the European Space Agency (ESA) and the UK Science Research Council, space science is divided between committees at the boundary of the solar system. Although this is a neat arrangement, solar-system science encompasses four almost completely distinct scientific fields, requiring different observational techniques and theoretical approaches. In this article it is not possible to do more than give some idea of the vigour of the research and indicate the principal directions it is taking.

Space plasma physics is concerned with the interaction between charged particles and magnetic fields. The solar wind plasma flowing outward from the Sun forms magnetospheres around the magnetised planets. The magnetospheres contain populations of high temperature plasma confined in the magnetic field.

The particle distributions and the magnetic field configuration of the Earth's magnetosphere are now well-known, but they are not enough to explain the first order operation of the magnetosphere as a plasma machine. The solar wind not only forms the magnetosphere; it is also its principal energy source. The energy is accumulated in the magnetic configuration of the magnetosphere and then released in an explosive event called the magnetospheric substorm, whose most obvious manifestation is the polar aurora. There are many unanswered questions about this process. How is the energy of the solar wind coupled into the magnetosphere and what controls the rate? How is the energy stored and what triggers its release?

The interpretation of satellite observations in such a dynamic system is hampered by the ambiguity between time variations of the whole system and spatial variations along the satellite orbit. The problem can be overcome by deploying a number of satellites in carefully coordinated orbits. This approach has been taken by the ISEE project which has one satellite stationed permanently in the solar wind and a pair of satellites moving close together through the outer magnetosphere to investigate the interaction between the solar wind and the magnetosphere. With the GEOS satellite in geostationary orbit they form a powerful combination to study magnetospheric dynamics.

Another fruitful approach is the comparison of solar system magnetospheres. Each one is dominated by a different effect: Jupiter by its rapid rotation; Mercury by the greater solar wind strength near the sun; and Mars by its atmosphere. The Earth's magnetosphere contains the elements in a dynamic balance. There will be an increase in the use of the plasma in the magnetosphere for plasma physics experiments, especially from Spacelab. The advantages include stable, fully ionised plasma, with no walls to influence the experiment.

The second field is the study of planetary atmospheres. There are now routine observations of the Earth's lower atmosphere for meteorological purposes; and there have been continuing investigations in the upper atmosphere in the regions accessible to satellites. But there have been relatively few observations of the stratosphere and mesosphere in between. A major thrust of atmospheric research is now being directed at the atmosphere between 10 km and 100 km through the international Middle Atmosphere Programme. Our ignorance of this part of the atmosphere became apparent when questions were raised about the influence of various pollutants—such as Freon from aerosol

cans and the exhaust of high-flying aircraft—on the ozone layer.

The chemical reactions which control the composition of the middle atmosphere are extremely complex. Much more information is required about the spatial distribution of various chemical species, the temperature structure, winds, waves and tidal motions before the controlling processes can be understood. All the available platforms will be used in this essentially exploratory work: aircraft, balloons and sounding rockets for in-situ measurements; and free-flying satellites and Spacelab to make global surveys by remote-sensing techniques.

As with magnetospheres, investigating the atmospheres of the other planets gives insight into the origin and evolution of the Earth's atmosphere as well. The two Pioneer Venus space probes will soon be returning detailed information about the dense and hostile Venusian atmosphere.

Solar physicists have made substantial use of space vehicles to study radiation from the Sun at wavelengths from UV to X-ray which do not penetrate through the atmosphere. Their next major project is NASA's Solar Maximum Mission, with 2 European instruments, which is designed to study solar flares during the next maximum of sunspot activity.

The scientific problems are similar to those of magnetospheric substorms. Energy is stored in the magnetic field of Sunspots and then suddenly released in the acceleration of charged particles. Similar questions need answering: how is the flare triggered, and how is the energy transferred to the particles? Since both flares and substorms seem to belong to the same class of plasma processes, any advance in one could assist the other and could also be relevant to other astrophysical and laboratory plasmas.

A second mission, the joint ESA/NASA Solar Polar Probe is going to look at the Sun from a different angle and study the three-dimensional structure of the solar wind. Two spacecraft will use the gravitational field of Jupiter to swing into heliocentric orbits normal to the ecliptic plane taking them over the north and south poles of the Sun respectively.

Finally, the field which has given some of the most spectacular results is the exploration of the planets themselves. US spacecraft are now en-route to Venus, Jupiter, Saturn and Uranus. So far the only European involvement has been by individual scientists but there are projects being discussed now which will be open for possible European participation.

I began by suggesting that the four disciplines within solar system science were grouped together just for administrative convenience. It is true that so far there has been little interaction from them. That may be because the links which must exist have not been fully recognised, but there is an extremely important unifying theme. Each field is concerned with one aspect of the physical environment which makes life possible here on Earth. Why has life developed here and apparently not on the other planets? Is there an important balance which we could unwittingly upset? The tremendous progress that has been made towards understanding all aspects of the origin and evolution of the solar system in the twenty years of research in space science, and the simultaneous realisation that human activities can have damaging effects on a global scale makes it clear that it is a field of research that we ignore at our peril. □

Insect molecular biology on Crete

from Walter J. Gehring

THIS summer biologists working on the molecular and genetic aspects of insect development converged on the island of Crete for an EMBO workshop held at Kolymbari followed by an international conference organised by the Hellenic Society for Biological Sciences in Heraklion. Crete was chosen because a new University is being established there and also to provide a stimulus to Greek biology. The meetings had a very special ambience which in part was created by the places at which the discussions were being held, which ranged from an ancient church and a Venetian fortress, to a night club and the beach. In the friendly atmosphere generated by our Greek hosts, the open exchange of information proved profitable for all the participants.

From the vast amount of new information presented in Crete only a few highlights can be mentioned.

Structural and functional organisation of the genome

The structural and functional organisation of the genome was the centre of discussion for much of the time. Among the unique genes, the silk fibroin gene has been cloned in bacterial plasmids (Y. Suzuki, Carnegie Institution, Washington) and analysed in detail, especially near the 5' end of the coding region, where one might expect the regulatory signals for transcription and processing of the fibroin messenger RNA. The 5' end of the gene was determined by hybridisation to mRNA which was specifically labelled at the 5' end, in the cap structure. The flanking sequences in front of the gene are AT-rich and contain sequences complementary to the 3' end of 18S ribosomal RNA. Like many other eukaryotic genes, the fibroin gene also contains a large intervening sequence some 1,300 nucleotides long, which is not present in the mature mRNA. Interestingly enough, the DNA sequences at the junction between the coding and intervening sequences are very similar in the mouse β -globin, mouse immunoglobulin gene and the silkworm

fibroin gene, which suggests that the enzymes involved in splicing the mRNA have conserved their specificity in the course of evolution. The notion that fibroin is coded for by a single gene is supported by recent genetic evidence (K. Sprague, Oregon). Genetic variants have been found which differ in the molecular weight of the fibroin. These variants show normal Mendelian inheritance as expected for a single gene, with codominant expression in heterozygotes. Since the protein and presumably also the gene sequence is internally repetitious, these variants in chain length are thought to be due to unequal crossing over.

Several research groups are focusing on the heat shock genes in *Drosophila*. *Drosophila* cells respond to a brief heat treatment by activating a small group of approximately nine gene loci which is reflected in the giant chromosomes by the appearance of specific heat shock puffs. These puffs are sites of intense RNA synthesis and accumulation of RNA polymerase. Under heat shock conditions transcription and translation of the remainder of the genome is reversibly turned off. Pre-existing polysomes disintegrate, a new population of polysomes carrying the newly synthesised heat shock mRNA appears in the cytoplasm, and a set of about eight heat shock polypeptides is synthesised. Obviously, regulation occurs both at the transcriptional and the translational level. This system has considerable potential for studying the coordinate control of a small group of genes. Several heat shock genes have been cloned. In particular, the genes coding for the major heat shock polypeptide of 70,000 daltons have been analysed. Both the analysis of deletions for the major heat shock puffs and evidence from *in situ* hybridisation with cloned DNA indicates that several genes coding for this polypeptide are located at two chromosomal loci, 87A and 87C, where the two major heat shock puffs are located. The restriction maps of the coding sequences at 87A and 87C are similar but not identical. The flanking sequences are very different. Heteroduplex mapping and cross hybridisation studies between the

sequences at 87A and 87C indicate homology of the coding regions and of two small regions apparently outside the coding sequences, near the 5' end of the genes. These sequences are obvious candidates for carrying regulatory signals.

The histone genes of *Drosophila* represent a tandemly repeated gene family (D. Hogness, J. Kemp, Stanford). The repeated element contains five histone genes in the order

H3 H4 H2A H2B H1,
← → ← → ←

where the underlining arrows indicate the direction of transcription of each gene. Such a cluster of five genes is separated from the next cluster by an AT-rich spacer of 1,200 base pairs, the entire element occupying five kilobase pairs. There are approximately 100 repeated elements which, however, do not form a single array, but are instead distributed among several arrays, separated by larger array spacers. Since the histone genes are present in several adjacent bands in the giant chromosomes, the subdivision into arrays may possibly reflect the band-interband organisation. The repeated element containing the five histone genes has been almost completely sequenced. Of particular interest are the short regions between the coding sequences for H2A and H2B, and between H3 and H4. The intergenic sequence between H2A and H2B spans 220 base pairs and contains a sequence of eleven base pairs which is present twice in opposite polarity. This sequence may be a promoter sequence, or part of a promoter.

Another gene family which has been studied extensively is that which codes for the chorion (eggshell) proteins of silkmoths (F. Kafatos, Harvard and Athens). In *Antheraea polyphemus* there are approximately 100 different chorion proteins synthesised and secreted by the follicle cells surrounding the oocyte in a 2-day period during egg development. Each protein is produced during a defined time interval *in vivo* and also in organ culture, indicating that the expression of the chorion structural genes is strictly regu-

Walter J. Gehring is Professor in the Department of Cell Biology at the Biozentrum, University of Basel.

lated according to a developmental program. The proteins can be divided into a few groups A to E. The proteins within each group share homologous amino acid sequences, but differ from each other by amino acid replacements, deletions or insertions. The difficulty of purifying individual mRNAs was overcome by constructing DNA sequences complementary to the mRNA mixture and cloning a pool of hybrid plasmids containing cDNA plasmids for individual messages. Sequencing of some of the cDNA clones revealed previously unsuspected homologies between limited regions of proteins from group A and B. The sequence data suggest that blocks of DNA sequences may be rearranged between genes in the course of evolution. The arrangement of these genes in the chromosomes is not known, but genetic data in the silkworm *Bombyx mori* indicate that the genes for all four classes are located on the second chromosome and probably are clustered (M. R. Goldsmith, University of California, Irvine). The transcription of these genes is being analysed by hybridisation of *in vivo* synthesised RNA to cloned cDNAs using a newly developed spotting procedure.

Transposable genes

Among the most intriguing genes are the dispersed repetitive gene families such as *copia* and *412* in *Drosophila* (D. Hogness, M. Young, Stanford). The *412* and *copia* elements are approximately 7.2 and 5.2 kb in length, respectively, and are found at 20 to 40 different chromosomal sites. The adjacent sequences are different at the different chromosomal locations. These sequence elements are homologous to abundant poly (A)-containing cytoplasmic RNAs. A curious feature of both families is that the elements are flanked by direct repeats of 0.5 and 0.3 kb respectively. The function of these flanking repeats is not known but by analogy with bacterial systems, one can speculate that these elements are translocated to different positions in the chromosomes by reciprocal recombination events which involve the repeated termini. This hypothesis can be tested in a case in which a *copia* element occurs within one unit of a tandemly repeated sequence, by comparing the sequence of the unit with and without the *copia* element. Preliminary evidence obtained by restriction mapping is consistent with the model. Evidence for transpositions of these elements at least on an evolutionary time scale comes from the observation that two wild-type strains differ with respect to the chromosomal location of these elements.

From genetic experiments, 'jumping genes' have been known for some time

RNA processing

from Andrew Travers

THE excision of intervening nucleotide sequences during the production of eukaryotic mRNA and tRNA molecules has recently highlighted the biological importance of post-transcriptional processing. This excision together with postulated subsequent ligation often involves the removal of an RNA sequence at least several hundred nucleotides long.

How do the processing enzymes achieve the exquisite accuracy that is a prerequisite for the maintenance of the continued function of the mature RNA molecules? One possible prokaryotic solution to this problem has recently emerged from the studies of Young and Steitz on the production of the 16S rRNA (*Proc. natn. Acad. Sci. U.S.A.* **75**, 3593; 1978). This rRNA is cotranscribed with the sequences for the 23S and 5S rRNA and is generated by RNase III cleavage of the precursor followed by secondary trimming. The RNase III cleavage sites are contained in the sequences flanking the 16S rRNA gene. By determining the DNA sequences of these regions Young and Steitz have discovered that the proximal and distal sequences are potentially capable of hybridising with each other to form a stem consisting of 26 base pairs. The individual strands of this stem are of course separated by a loop of about 1,700 nucleotides containing the entire 16S rRNA gene. The biological importance of such a structure is given credence by the observation that both proximal, and distal RNase III cuts are contained within the base-paired region. Further, RNase III may require a double helical region of at least 9 base pairs both 5' and 3' to the point of scission, a structure which is lacking in the immediate neighbourhoods of the scission sites. Thus the most probable interpretation is that a site for RNA processing can be generated by the interaction of distantly spaced complementary RNA sequences. The authors suggest that an analogous process may operate during the production of

eukaryotic messenger RNAs

Cleavage by RNase III does not by itself generate the normal 16S rRNA sequence, yielding only a 17S precursor. For production of the mature 16S RNA two or more additional processing enzymes are required. One recent addition to the family is the endonuclease RNase M16 which cleaves the 16S precursor immediately proximal to the normal 5' end of the 16S RNA molecule (Dahlberg *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 3598; 1978), while yet another enzyme is apparently required for the production of the mature 3' end (Hayes & Vasseur, *Eur. J. Biochem.* **61**, 443; 1976).

A further quirk in the enzymology of RNA processing is provided by the discovery that RNase P, first detected as the activity required for the production of *su⁺* tRNA (Altman & Smith *Nature new Biol.* **233**, 35, 1971) contains a specific RNA moiety 350 nucleotides long in addition to the expected protein (Stark *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 3717; 1978). As normally purified this highly unusual enzyme contains about 80% RNA by mass. Furthermore the RNA component seems to be essential for nuclease activity. This requirement for the RNA molecule could be trivial. For example, it might be needed to stabilise an active conformation of the protein component. Alternatively the authors suggest the biologically more interesting possibility that the RNA molecule may itself participate in the recognition of the RNase P cleavage site by a mechanism involving direct RNA-RNA interaction. Implicit in such a model is of course the potential for varying the substrate specificity of the enzyme by simply changing the sequence of the RNA moiety. Again, if this enzyme is of universal occurrence such a capability might have important implications in the production of eukaryotic RNA species.

Andrew Travers is at the MRC Laboratory of Molecular Biology, Cambridge.

in *Drosophila*. For example, several transposable elements carrying the *white* locus have been described. *White* was the first mutant to be found in *Drosophila* and 'traditionally' it maps on the X chromosome. However, fly stocks have been found in which the *white* locus is transposed to different chromosomal sites and transpositions are observed in these laboratory stocks. At the meetings, the isolation of a

hybrid plasmid containing complementary sequences to such a transposable element was reported (W. Gehring, Biozentrum, Basel). The element carries both the *white-apricot* allele and the neighbouring *roughest* gene. This plasmid is obviously of great interest for the study of transposable elements in *Drosophila*. It may also provide a general tool for the isolation of genes with no known biochemical function.

Since the transposable element causes mutations by inserting into genes, the flanking gene sequences can be isolated by using the hybrid plasmid complementary to the transposable element as a probe. Alternative methods for gene isolation in general were discussed, in particular the possibility of starting from a DNA sequence which maps close to the gene to be isolated and 'marching' along the chromosome by isolating overlapping DNA sequences (S. Artavanis-Tsakonas & Hogness, Stanford). The present rate of 15 kb per month may be accelerated by using vectors which can accommodate very large inserts of donor DNA.

Polytene chromosomes

The structure and function of polytene chromosomes remains a controversial field to which the recent studies, using fluorescent antibodies to localise RNA polymerases and other chromosomal proteins, have added a new dimension. Classical genetic studies indicate a strong correlation between genes and bands, but the analysis is more or less confined to unique essential genes and it is difficult to estimate what fraction of the genes escapes detection in these genetic tests. In contrast to the hypothesis that the boundary between bands and interbands in the giant chromosomes is defined by specific DNA sequences, a more dynamic model has been proposed on the basis of fluorescent antibody studies (E. Bautz, Heidelberg). This model assumes that puffs and interbands represent the actively transcribed fraction of the genome which varies with the stage of development and between tissues. The well-founded hypothesis that puffs are activated genes has obtained further support by the elegant demonstration of active units of transcription in Balbiani Ring 2 of *Chironomus* by the Miller spreading technique and electron microscopy (B. Daneholt, Karolinska Institute, Stockholm). It appears that there is only one active DNA sequence of 37 kb being transcribed in a chromosome which, on the basis of microspectrophotometry, contains as much as 470 kb.

Endocrinology

Insect endocrinology has also received a new impetus. A plant ecdysone, ponasterone A, has been found with about 50 times the activity of the insect hormone β -ecdysone. Its biological action seems to be identical to that of the natural moulting hormone. Because ponasterone A can be labelled to high specific activity by catalytic tritiation of an unsaturated precursor, stachysterone C, it can be used to identify putative ecdysone receptors, which so far has not been possible (M.-A. Yund, Berkeley). Data from

several laboratories indicate binding constants of the order of 10^8 to 10^9 M. A similar binding constant has been reported for a juvenile hormone receptor. Moulting hormones have now been discovered in the ovaries of several insects and intermediates in the biosynthesis of ecdysone are being isolated and characterised (J. Hoffmann, Strasbourg). The peaks of ecdysone concentration coincide with the time of secretion of the egg shell during oogenesis, and with the time of cuticle formation during embryogenesis. Vitellin, the major yolk protein, seems to be under hormonal control by juvenile hormone in most insects with the exception of mosquitoes and possibly other diptera, where ecdysone seems to take over this role. In locusts, vitellin is a glycolipoprotein of 550,000 daltons which is derived from a precursor, vitellogenin, that is synthesised in the fat body (G. Wyatt, Kingston, Ontario). *In vitro* studies indicate that initially two polypeptides of 265,000 and 250,000 daltons are synthesised which may represent products from two different genes. The labelled precursor can be chased progressively into a group of smaller polypeptides of 140,000 to 52,000 daltons. Vitellogenin synthesis is induced by juvenile hormone, secreted by the fat body and transported to the oocytes, which makes the system analogous to vitellogenin synthesis in vertebrates. Since methods are now available for the isolation of hormone-inducible genes and several ecdysone-inducible genes have already been isolated in *Drosophila* (Kemp & Hogness, Stanford), one can expect rapid progress in this area.

In the area of insect cell culture there has also been considerable progress. *Drosophila* cell lines have now been established from several mutant strains (H. P. Bernhard, Biozentrum Basel), and successful cell fusion has been announced (C. Wyss, ETH Zurich). Perhaps the most important recent contribution has been the establishment of a mutant cell line with the haploid chromosome number (G. Echallier, Paris).

Although there has been an extensive search for regulatory mutants, *Drosophila* geneticists have so far failed to provide conclusive evidence for the existence of regulatory elements controlling the activity of structural genes in development. It may be that our ideas have been too greatly influenced by models developed for prokaryotic systems. Interesting new results on genes controlling compartment formation in imaginal disks (T. Kornberg, University of California, Los Angeles; P. Lawrence, MRC Laboratory of Molecular Biology, Cambridge) and mutants interfering with sex de-

termination were presented (R. Nöthiger, Zürich). If such genes can be isolated by molecular cloning techniques, it may become possible in the future to unravel controlling mechanisms operating at these higher levels.

The workshop and the conference were among the best meetings that I have attended, especially in promoting the dialogue between scientists working in related fields, and our Greek hosts merit special thanks for providing an ideal setting which made these meetings so pleasant. □

Ice dynamics

from a Correspondent

Is man's effect on world climate likely to precipitate a catastrophic rise in world sea level as suggested by Mercer (*Nature* 271, 32; 1978) and is a major surge of the Antarctic ice sheet still considered possible by glaciologists? These and other questions were discussed during the recent International Glaciological Society's Symposium* on 'The dynamics of large ice masses' at Carleton University, Ottawa. Thanks to the associated 'Symposium on glacier beds: the ice-rock interface' organised under the National Research Council of Canada at the same location during the preceding week, there were many healthy exchanges between glacial geologists who had studied the effect of ice dynamics in the past, glaciologists studying present day glaciers and ice sheets and an increasing number of glaciological modellers. Most participants benefitted from attending both symposia, a happy juxtaposition of meetings since the glacier bed is the inadequately understood base of glacier dynamics in more ways than one.

It is apparent that while our understanding of the internal deformation of ice sheets is advancing along satisfactory lines, our knowledge of how much sliding takes place at the glacier bed, how much it is controlled by rock debris in basal ice, by basal water pressures and by pressure melting and regelation are still far from adequate. Until this is cleared up, modellers will lack guidance on how to treat the base of the ice sheets of Greenland and Antarctica. In this connection, long awaited reports on the debris-laden ice cores from the base of the ice sheets at Camp Century, Greenland and Byrd Station, Antarctica were of special interest.

A. J. Gow and W. Sheeby (US Army's Cold Region Research and Engineering Laboratory, Hanover, New Hampshire) and S. Epstein (Caltech) showed that the lowest 4.83 m of the core from Byrd Station contrasted with

* Held 21-25 August, 1978.

ice immediately above through its very low content of dissolved air, the presence of rock particles ranging from clay size through sand to pebbles and cobbles, and in its oxygen isotopic composition. The latter was around 4‰ lower in $\delta^{18}\text{O}$ values in the basal ice, and more variable than in the ice above. Thus when one allows for fractionation effects it seems that the basal ice that was formed by refreezing of the melt water was of fairly local origin, but it is not clear whether freezing took place in a single period or was episodic. Melt water was present beneath the ice when the base was reached in 1968.

Whereas debris weight percentages of up to 15.7% were present in the basal ice from Byrd Station, Susan Heron and C. C. Langway (Buffalo University) found an average debris concentration of only 0.24% in the bottom 15.7 m of the 1966 core from Camp Century. This contained over 300 alternating bands of clear and debris-laden ice. Although the basal ice temperature is now -13°C , they conclude that the debris was incorporated by freezing of subglacial water over a basal till. There was only one pebble in the Camp Century ice, the remaining fine debris being either distributed throughout the dirty ice layers or included in the form of pebble-sized aggregates of fine particles picked up from the basal till. In contrast to the Byrd core, the gas concentration in the basal ice at Camp Century was about half that at higher levels. The gas showed traces of methane, high CO_2 levels, low O_2 levels and enrichment of argon. It was suggested that although air may have been excluded during freezing, its composition indicated subsequent diffusion into the basal ice.

As with glacier beds, the main advances in our understanding of the dynamics of the Antarctic ice sheet are coming from field measurements often involving new techniques. Radio echo mapping from long range aircraft, satellite altimetry and Doppler position fixing as well as more conventional survey methods are providing much better knowledge of the form and flow of the polar ice sheets than seemed possible a few years ago. N. Young (Melbourne University, Australia) who took part in Soviet traverses over the east Antarctic ice sheet during the past two summers found that ice velocities measured by satellite Doppler techniques agreed with calculated balance velocities within an accuracy of 20% in a region of around one million km^2 between Mirny Station and Dome 'C'. Other reports indicate that areas feeding the Lambert and Shiraze Glaciers may not be in balance, while

evidence discussed by K. Rose of the Scott Polar Research Institute suggested that an ice stream feeding the Ross Ice Shelf from Byrd Land may have surged in the not too distant past. The general consensus appeared to be that while surges of individual glacier basins in Antarctica might occur, the idea of a single massive surge of 10 to 20% of the total ice mass of Antarctica as a cause of ice ages (Willson *Nature* 201, 147; 1964) was losing ground.

Laboratory studies on ice cores from Law Dome by D. S. Russell-Head and W. F. Budd (Antarctic Division, Department of Science, Melbourne) showed that flow (shear strain) rates in ice with strongly aligned C axes were typically three to five times faster than in randomly-oriented polycrystalline ice, whereas crystal size had little effect on flow rates. These results matched well with measurements of borehole inclination from the same locality. It is becoming clear that the variation of horizontal ice velocity with depth is more complex than expected and that the accuracy of age-depth relationships in ice cores based on ice flow models is limited by these factors.

The above did not, however, deter the modellers who use computer simulations to increase our understanding. Of these, a catastrophe model of the palaeoclimate by D. R. MacAyeal (University of Maine, Orono) that considered changes of insolation, sea level and isostatic depression of the glacier bed helped to explain the sudden transitions between ice-free and ice age conditions.

In addition to ice sheets, floating ice shelves and sea ice were discussed in half day sessions. Towed side scan sonar records from a ship obtained by O. Orheim of Norsk Polarinstitutt showed both basal scour of the sea bed by icebergs and a fascinating pattern of irregular melting at a depth of 100 to 200 m beneath straight cliffs of the ice front. Discussions of the mechanical and thermal stability of ice shelves and marine ice sheets indicate that before any sudden climatic warming would release the ice sheet of West Antarctica and affect sea level there would be a delay of some hundreds of years. After this, considerable progress in modelling of Arctic pack ice seemed relatively mundane, if no less important climatologically.

Overall, it is becoming clear that to advance from a few elementary but over-simplified concepts of glacier behaviour to a detailed understanding of the dynamics of ice sheets involves more complex investigations than was commonly realised a decade ago, but much progress is being made. This is significant since hydroelectric projects

and the development of Arctic oil involves judgement on glaciological matters that are of major importance to industry. □

New magnetic structures in the light rare earth metals

from S. B. Palmer

RECENT weeks have seen two significant developments that have cast new light on the magnetic behaviour of the rare earth elements, praseodymium and neodymium. At room temperature both elements are paramagnetic with localised magnetic moments produced by the electrons in the partially filled 4f shell. In the majority of the rare earth metals the exchange interaction is sufficiently strong to produce magnetic order at low temperatures although the oscillatory, long range nature of the exchange interactions results, in many cases, in complicated modulated magnetic structures. Each magnetic ion also experiences an electrostatic field with the symmetry of the crystal lattice: this crystal field interaction opposes the exchange by favouring a uniform arrangement of the moments. For both neodymium and praseodymium the crystal field and exchange energies are comparable, but in neodymium the exchange energy is sufficiently strong to produce magnetic ordering below 20 K.

The magnetic structure of neodymium has been a mystery since the initial neutron diffraction measurements of Moon *et al.* (*J. appl. Phys.* 33, 1041; 1964) carried out at Oak Ridge. The double hexagonal close packed (dhcp) structure has two separate sublattices, one with cubic and the other with hexagonal symmetry. Moon proposed that at 20 K the ions on the hexagonal sites ordered antiferromagnetically. These sites form planes lying perpendicular to the hexagonal axis and in a particular basal plane the magnetic moments, according to Moon *et al.*, are confined to the plane and oriented along the crystallographic *b* direction. The moments are sinusoidally modulated with the *q* vector of the modulation in an *a* direction, at 90° to the moments.

This model, however, was inadequate to explain all the features of both Moon *et al.*'s results and the more recent work of Lebech and Rainford (*J. Physique* 32, 370; 1971; *Proc. Int. Conf. Mag. Moscow* 3, 191; 1974.) A

S. B. Palmer is in the Department of Applied Physics, University of Hull.

Fig. 1 Magnetic structure of neodymium for $\alpha=0^\circ$. The basal-plane components ($\uparrow$) of the spins in the A layers centred at the atomic positions of the undistorted lattice.

better fit to the experimental data could be obtained if it was assumed that the cooperative order on the hexagonal sites induced magnetic order on the cubic sites although the results were still far from satisfactory.

The report by Bak and Lebech (*Phys. Rev. Lett.* **40**, 800; 1978), of a magnetic structure that fits all the experimental results brings relief to many solid state physicists who have spent long hours attempting to unravel the neodymium puzzle. The novel magnetic structure of the hexagonal sites is shown for one basal plane in Fig. 1 where the magnetic moments are modulated in the three equivalent ' a ' directions simultaneously, hence the name of 'triple- q ' modulated magnetic structure. The work of Bak and Lebech in Denmark involved experimental proof that the magnetic phase change at 20 K was of second order, hence allowing Landau symmetry arguments to be used with renormalisation group theory to predict that the three different equivalent q vectors are present simultaneously rather than contained in separate domains as in the structure of Moon *et al.*

Associated with the magnetic structure shown in Fig. 1 are lattice distortions that are identical in form except for a phase difference of 90° . Initial estimates indicate that these distortions may well be of the order of a few percent and as such should be detectable by X-ray scattering studies.

Measurements of specific heat, elastic constants, magnetoresistance and neutron diffraction have all revealed a multitude of phase changes as a function of applied field in the temperature range 1-20 K. The extension of Bak and Lebech's model to high fields is eagerly awaited.

In contrast to neodymium, praseodymium is fascinating, not for the order it exhibits, but for the magnetic order it nearly exhibits. Experiments on single crystal praseodymium demonstrate that it remains paramagnetic down

to 30 mK: the exchange is about 90% of the critical value for magnetic ordering. In contrast polycrystalline praseodymium, highly strained because of anisotropic thermal contraction, orders antiferromagnetically at 25 K. The addition of 3% neodymium to single crystal praseodymium produces order below 6 K. Because of the large orbital angular momentum of the Pr ions, there is a powerful coupling between the lattice and spin systems. Jensen's analysis (*J. Phys. C* **9**, 111; 1976) of this magnetoelastic coupling led him to predict that, at 4.2 K, a relatively modest pressure of 1,000 bar applied along the crystallographic a direction would, by distorting the basal plane, change the delicate balance between exchange, crystal field and magnetoelastic energies and induce magnetic ordering. In a recent investigation of these predictions McEwen *et al.* (*Phys. Rev. Lett.* **41**, 343; 1978) have carried out (at the Institut Laue-Langevin, Grenoble) a series of careful neutron inelastic scattering studies of praseodymium as a function of uniaxial stress applied along the a axis. They found that as the stress was increased the

lowest energy magnetic excitation dramatically decreased, heralding the antiferromagnetic order which was established at 800 bar. The presence of the ordered phase was confirmed by the observation of elastic satellite reflections corresponding to a long-range magnetic structure. At 800 bar the Néel temperature was 7.4 ± 0.4 K. On removal of the stress the magnetic satellites were absent and the exciton dispersion curve was identical to that of previous workers and to the curve obtained before stressing took place. Both these results indicate that there was no residual stress left in the sample and the process was completely elastic.

The magnetic structure postulated by McEwen *et al.* is a basal plane modulated structure, identical to that of Pr - 3% Nd and reminiscent of the neodymium structure discussed above. Jensen's elegant theories, which have already led to quantitatively accurate explanations of neutron inelastic scattering studies of exciton phonon coupling, field dependence of elastic constants and magnetostriction, seem to have been vindicated again. □

Sun-weather effects

from Roger H. Olson

MOST of the papers presented at a recent conference on Solar-Terrestrial Influences on Weather and Climate* reflected the fact that Sun-weather research is still pretty much in the empirical stage. There is even disagreement on the details of many of the empirical findings. For many years the conventional wisdom has held that Sun-weather effects were stronger in winter than in summer, and stronger in the auroral zone than in low latitudes. However, this may be just a reflection of the fact that changes are more dramatic in high latitudes and in winter, and empirical studies tend to focus on the more dramatic effects. As far back as 1965, H. C. Willett of the Massachusetts Institute of Technology pointed out that, when properly normalised, the weather data show stronger responses to solar signals in summer and in low latitudes. Although there is still conflicting evidence, Willett's ideas received strong support from several investigators. There was also support for the idea that the X-ultraviolet portion of the solar spectrum may be more important than the particle emission, that is, solar proton events.

As for low energy solar particles, the so-called auroral particles, there was relatively little discussion of geomagnetic-weather effects. One possible reason is that in using geomagnetic data there is the danger that a small part of the geomagnetic signal could be caused by a weather disturbance. Although this danger is rather slight, many investigators prefer to use solar signals that are unmistakably solar, such as solar flares and plages, sunspots, and magnetic sector boundaries. One particular class of geomagnetic disturbances did receive special attention, however—the Forbush decrease events. In a Forbush decrease, the magnetic disturbance causes a decrease in cosmic ray flux throughout the whole depth of the atmosphere, including the surface layers. Thus, in seeking mechanisms to explain the various Sun-weather effects observed, the Forbush decrease is becoming more and more interesting.

One theme that ran through the conference was the importance of Sun-weather effects in weather forecasting. In 1977 M. F. Larsen and P. M. Kelley of Cornell University found that the accuracy of US weather forecasts took a dip one day after solar sector boundary crossings. Following their lead, R. Reiter (Institute for Atmospheric Environmental Research of the Fraunhofer Society, FRG) reported that German forecasts suffered a

* The first Ohio State University Sun-Weather Conference was held on the campus of the University from 24-28 July, 1978. The conference was organised and chaired by T. A. Seliga, Ohio State University, and B. M. McCormac, Lockheed Palo Alto Research Laboratory. It is hoped that this type of conference can be repeated every two to three years.

similar fate. J. W. King (Appleton Laboratory, UK) reported similar findings for British forecasts. All these results cover relatively short time spans and limited geographical areas, and thus should be treated as tentative, but highly suggestive.

There was a healthy degree of skepticism expressed by several speakers. W. O. Roberts (Aspen Institute for Humanistic Studies, Boulder) stressed that, in spite of the virtual certainty that Sun-weather relationships exist, we desperately need rigorous theoretical studies and models to explain them. J. Namias (Scripps Institution of Oceanography, La Jolla) chose to focus on one meteorological parameter, namely drought. He stressed the importance of understanding the full implications of the physical causes of droughts in attempting to correlate drought with solar activity. Interestingly enough, although drought is typically associated with anticyclones, he felt that the best place to look for Sun-weather influences is in cyclonic activity. His attitude is perhaps typical of many highly skilled and experienced meteorologists—namely that Sun-weather research, in spite of its long and frustrating history, deserves careful scrutiny. The chief skeptic by far, was A. B. Pittock, temporarily of the University of Arizona. He cast strong doubts on many published reports of correlations between weather and the various solar cycles (such as 27 days, 11 years and 22 years). The 27-day cycle was also attacked by others, who pointed out that it is difficult to distinguish between 27-day solar and lunar effects. Pittock had little quarrel with some of the short-term correlations which have been reported recently.

As regards mechanisms, the cupboard is not entirely bare. Perhaps the most popular was the thunderstorm mechanism, discussed by R. Markson (Massachusetts Institute of Technology) (see *Nature* 273, 103; 1978) and others. He regards the thunderstorm, and its associated high resistivity to vertical electrical currents as a valve controlling the whole electric circuit of the atmosphere. Solar flares, and possibly Forbush decreases, can modify the resistivity above thunderstorms, leading to profound changes in the global circuit. This could feed back into the physics of the clouds, affecting precipitation patterns and affecting gross features of the atmospheric energy balance. Empirical evidence supporting this idea was furnished by Markson himself, by R. Reiter, and

by M. Lethbridge (Pennsylvania State University). They all presented evidence that thunderstorm frequency is related to solar signals such as flares and solar sector boundaries.

Ozone was also mentioned as a possible trigger mechanism. M. B. Schlesinger (Oregon State University) suggested that an initial ozone increase, caused by solar activity, could lead to circulation changes, which in turn would lead to advective changes in ozone concentration, this leading to a positive feed-back. Many others agreed that some sort of ozone mechanism might be useful. Another possible feed-back mechanism was suggested by E. C. Kindle (Old Dominion University, Norfolk, Virginia) and also elaborated by others. This involves the Charney-Drazin effect, which operates on about a 10-day time scale, a typical time scale for some reported Sun-weather effects. If the speed of the middle latitude westerlies is decreased, this allows greater penetration of tropospheric wave energy up into the stratosphere. Thus if the troposphere is subjected to an influence (possibly a solar influence) that causes it to lose kinetic energy, the feed-back mechanism

will cause it to lose even more energy through dissipation to the stratosphere.

The symposium ended with a number of resolutions. One involved a request to international scientific organisations, such as ICSU, to place the Sun-weather problem high on the list of future projects. Another was to decry the tendency for old, reliable data sets to be threatened with extinction, due to retirement of key personnel or lack of funding. Examples of data sets which are either threatened or actually ended include the Zurich sunspot observations, the Ottawa centimetric radio observations, the Greenwich daily sunspot drawings, and the McMath daily plage observations. These have been of great value both to research workers and to those engaged in operational solar-terrestrial problems. As an example of the latter, there were reports given by two commercial weather forecasters who use solar data in making their forecasts. Although it may be regarded as premature, even by some enthusiasts, to use solar flares, for instance, in routine weather forecasting, the fact that it is being done underscores the need for a serious study of the problem.

Therapeutic agents for sickle cell disease

from M. F. Perutz, J. Rosa and A. Schechter

At a recent workshop in Paris* the molecular and cellular bases of sickle cell disease and possible new approaches to its therapy were discussed.

M. F. Perutz (MRC Laboratory of Molecular Biology, Cambridge) reviewed X-ray diffraction and electron microscope studies of the gels of deoxyhaemoglobin A that precipitate in the red cells of patients with sickle cell anaemia. These gels consist of fibres of 20–22 nm diameter, each made up of several filaments of 6 nm diameter in which single haemoglobin molecules are strung together like pearls. The structure of the contacts between successive molecules in these filaments is known in atomic detail from X-ray analysis of crystalline deoxyhaemoglobin A in which the molecules are strung together in the same way. Sickling is probably caused, first, by the pairwise aggregation of such filaments, as in crystals of deoxyhaemoglobin S (deoxyHb S), where the valines of one filament touch nonpolar side chains between helices E and F β in the neighbouring filament of the pair, and then by the aggregation of several such pairs to form a fibre. Dykes *et al.* proposed

that each fibre is a rope made up of 14 filaments (*Nature* 272, 506; 1978); A. Klug suggested that this number may arise from the winding of six pairs of filaments around one central pair.

W. Love (Baltimore) reported that the resolution of the X-ray analysis of single crystals of deoxyhaemoglobin S had been raised from 5.0 to 3.0 Å, good enough to distinguish individual residues. The new map confirms that the structure of deoxyHb S is the same as that of deoxyHb A, except that the substitution of valine for glutamate 6 β may have forced the first turn of helix A to a conformation different from that in deoxyhaemoglobin A. B. Magdoff-Fairchild (New York) reported her exciting discovery that oriented, paracrystalline preparations of sickled cells or deoxyhaemoglobin A can turn into bundles of crystals isomorphous with those analysed by Love and his colleagues. The intensity distribution in the X-ray diffraction patterns of these crystalline bundles is similar to that of oriented gels, suggesting similar molecular arrangements. This raises hopes that by combining information from crystals and gels we may be able to find out more about the structure of the contacts between molecules in the

* Held on 19–21 July and sponsored by INSERM and the US National Institutes of Health

gels than has been possible by studies of gels alone.

At constant temperature solutions of deoxyHb S remain liquid for long periods until they suddenly gel. The delay is exactly reproducible and is inversely proportional to high powers of the temperature and haemoglobin concentration (*Proc. natn. Acad. Sci. U.S.A.* **71**, 4864; 1974). W. Eaton (Bethesda, Maryland) proposed to use this phenomenon for testing anti-sickling drugs. To make the disease significantly less severe, a drug would have to increase the delay 10–100-fold, equivalent to a 1.06–1.17-fold increase in the solubility of deoxyHb S or a 1.5–4-fold decrease in intracellular Hb concentration or a 4–7-fold increase in oxygen affinity. These are stiff requirements. E. R. Heuvels and M. Rosemeyer measured the antigelling properties of Hb A, F and A₂ when added to Hb S, and found that the antigelling effect rises in that order. This suggests that activation of the gene for Hb A₂ would have a more potent antisickling effect than activation of the gene for Hb F.

Cell studies

Studies of whole normal and sickled cells were reviewed next. J. Hoffman (New Haven) discussed the distribution of diffusible ions and control of cell volume in normal erythrocytes, and the use of fluorescent dyes to study the intracellular milieu. Such studies are very relevant in view of the steep dependence of the gelling delay on haemoglobin concentration. M. Mohandas and N. Bessis (Paris) used anisotropy of laser light scattering to measure the deformability of red cells sheared between the concentric cylinders of a viscometer. This method could be used to measure the degree by which antisickling agents diminish the stiffening of deoxygenated sickle cells.

The physiology of the sickle erythrocyte is more complex than that of Hb A solutions. Recent technical advances are now allowing their oxygen equilibria to be measured. R. Bookchin (New York) found that the Bohr effect of sickle cells is steeper than that of normal ones and that 2,3-diphosphoglycerate, the intracellular oxygen regulator, increases gelation merely by lowering the oxygen affinity and not, as had been reported, by making deoxyHb A less soluble. R. Benesch and R. E. Benesch (New York) measured the oxygen affinity of Hb A as a function of haemoglobin concentration and found a discontinuity at

the point of gelation corresponding to the minimum gelling concentration. The concentration at which this discontinuity occurs could be used as a measure of the antigelling properties of drugs. If any drug inhibited sickling without raising the oxygen affinity of solutions which are too dilute to gel, then this would prove that it acted on the intermolecular contacts.

Antigelling and antisickling agents

Compounds being tested *in vitro* as antigelling or antisickling agents were discussed next. These may act by more than one mechanism, but can be classified according to their primary effects. The first class consists of modifiers of Hb A which raise the oxygen affinity. The prototype of such reagents was KNCO which proved too toxic for oral therapy. According to L. Kraus carbamylphosphate reacts with haemoglobin in the same way as cyanate, but the unreacted fraction may be less toxic as a result of enzymatic degradation. Imidoesters, both bifunctional dimethyladipimidate (B. Lubin, Oakland, California) and monofunctional methylacetimidate (T. Gabuzda, Philadelphia) decrease sickling by raising the oxygen affinity; so does cystamine which reacts with cysteines 93β (Y. Beuzard & J. Rosa, Paris). Among disulphide reagents cystine dimethyl-ester reacts with the same groups, increases the oxygen affinity and has antisickling properties demonstrable in single erythrocytes (D. L. Currell, Rome). The toxic nitrogen mustards react with histidine 2β which is one of the diphosphoglycerate binding groups. (E. Roth, New York).

The second class consists of modifiers of intermolecular contacts in deoxyHb S fibres. J. Manning (New York) has found that glyceraldehyde inhibits sickling, probably by reaction with a specific lysine not yet determined. It also acts on the membrane. Other compounds in this class interact non-covalently, such as the alkylureas studied by R. Nagel's group (New York) which are more potent inhibitors than urea itself. A. Schechter (Bethesda) has sought stereospecific amino acids or peptides that inhibit gelation and found that aromatic amino acids or peptides containing aromatic amino acids, but not the sickling peptide (residues 1–16β), have antigelling properties. C. F. Poyart (Paris) found that methane, ethane, propane and butane increased the oxygen affinity by 10–15%, propylene by 25% and butane by 50%; these agents may also act on the intermolecular contacts. A. Cerami (New York) reported experiments with n-carboxyaspirindimethylester which reacts with an as yet undetermined group.

The final class of compounds dis-

cussed were modifiers of the whole erythrocyte. G. Brewer (Ann Arbor) described clinical and laboratory studies of Zn acetate as an antisickling drug and C. Natta (New York) discussed DBA(3,4-dihydro-2,2-dimethyl-2H-1-benzopyran-6-butyric acid).

Many of these compounds are too toxic for oral use and would have to be administered extracorporeally, by removing the red cells from the circulation, reacting them with the drugs, and putting them back again. S. Balcerzak (Columbus) has tested extracorporeal administration of cyanate to erythrocytes of dogs and two baboons and found no toxic effects in periods of up to one year. D. Diederich (Kansas) tried extracorporeal cyanate treatment on about 10 sickle cell patients and found a reduction in crises during treatment, as compared to before and after.

According to W. Rosse's (Durham, North Carolina) review of the American clinical trials of orally administered urea, alkali and cyanate, none of these reduced the severity or frequency of sickle cell crises, but the trials helped to establish reliable criteria for evaluating new therapies. At a final round table conference clinicians from West Africa and the USA dwelt on the great variability of the disease, and the absence of reliable information concerning its mortality, morbidity and clinical manifestations, especially in Africa and the Middle East. They were also concerned about the ethical problems of trying anti-sickling drugs on patients. They would not try them on children and felt that even adults might be better helped by conservative treatments. □

A hundred years ago

FROM the 16th to the 18th of August the city of Cartago in Costa Rica, in Central America, was visited by five distinct shocks of earthquake. No particular damage was caused. What is to be noticed in the meteorological result: that the weather was changed, being attended by heavy showers that flooded the rivers. In all earthquake countries it is believed the weather is affected by such phenomena, and it is desirable that observations should be recorded, showing the influence of earthquakes on weather. It has been alleged that the Comrie earthquakes in Perthshire came on after rains and floods of the river.

The International Ultraviolet Explorer (IUE)

The following eight papers deal with the International Ultraviolet Explorer (IUE), a joint project of the National Aeronautics and Space Administration (NASA), the European Space Agency (ESA) and the Science Research Council (SRC). The first paper describes the overall project and concept. The second deals with its performance in orbit as assessed during the commissioning phase following the successful launch of 26 January 1978. In addition to engineering switch-on, sub-system tests, optimisation and calibrations, that commissioning phase included astronomical observations of a set of high-priority targets as an insurance against premature failure of the system. What is 'high priority' is always a matter of judgement, and in this case that judgement was made by an international science commissioning team drawn mainly from the project staff of the three agencies but also including scientists from the general community. The results of those high-priority observations and their subsequent analysis are presented in the final six papers of this series. It should be stressed that these observations were made immediately after switch-on, that is before the system had been fully optimised or calibrated, and that the data were reduced in the very earliest phases of the image processing system. Nevertheless they clearly indicate the potential of IUE and provide a range of new and exciting data in many areas of astronomy.

In addition to the authors listed on the following papers, many people have made essential contributions to this project in all its stages, from conception and approval through hardware production and launch to the recent commissioning and operational phases. To all those people, in the government agencies, research institutes, universities and industry of many countries, the authors extend their thanks and gratitude. These papers were submitted on 9 August 1978.

The International Ultraviolet Explorer satellite operates as an astronomical observatory to provide both high and low resolution UV spectra of sources other than the Sun. The spacecraft, its instrumentation and the ground control system are described.

THE International Ultraviolet Explorer (IUE) was launched successfully on 26 January 1978, from Cape Canaveral, Florida. The satellite was developed to provide a general facility for observing ultraviolet (UV) spectra of astronomical sources over the wavelength range from about 1,150 Å to 3,200 Å. The project has been a joint undertaking in which the US National Aeronautics and Space Administration (NASA) provided the spacecraft, the optical and mechanical components of the scientific instrument, the US ground observatory and spacecraft control software; the UK Science Research Council (SRC) in collaboration with University College London (UCL) provided the television cameras used to record the spectroscopic data; and the European Space Agency (ESA) provided the solar arrays and European ground observatory. The image processing software was developed jointly by NASA and the SRC's Appleton Laboratory. The satellite has been placed in geosynchronous orbit over the Atlantic Ocean and is operated for 16 h each day, for NASA sponsored observers, from the US ground observatory located at the Goddard Space Flight Center (GSFC) near Washington, D.C., and for the remaining 8 h by ESA, for ESA and UK sponsored observers, from the European ground observatory located near Madrid.

Here the spacecraft and its instrumentation are described. In the following series of papers IUE's performance in orbit will be discussed¹, and the initial results from early observations taken during the satellite checkout and commissioning period reviewed²⁻⁷.

Design concepts

It was decided that a high spectral resolution of the order of 0.2 Å would be required to study the atmospheric characteristics of bright stars and planets and that a lower resolution of about 6 Å should be available to obtain information on faint sources. In addition, two other requirements were fundamental in determining the design of the scientific instrument and of the spacecraft to support it: first, the instrument should be able to record simultaneous data over large spectral ranges and, second, the spacecraft should be able to take maximum advantage of the observer's real-time judgement concerning the quality and content of his data.

The first suggests a spectrograph using an imaging system, such as a television camera, capable of integrating the spectrum. A spectrograph with echelle optics gives a compact spectral

format with high dispersion and, since the echelle image consists of many adjacent spectral orders displayed in a closely spaced array, it makes efficient use of the field of view of a television camera. To achieve adequate resolution, the total spectrum must be split into two ranges, from 1,150 Å to 1,950 Å and from 1,900 Å to 3,200 Å, and so two cameras are required to record the full spectral range. The observing efficiency is hardly affected by this split, as two exposures are usually required to expose, optimally, both the long and short wavelength spectra.

The second requires good communication between the spacecraft and the observer so a geosynchronous orbit was chosen. The IUE orbit allows continuous real-time control from the NASA control centre and at least 10 h each day from the ESA control centre. The arrangement is fundamentally different from low altitude orbiting observatories which have to acquire data while remote from ground control. In the case of IUE, control and performance monitoring are exercised continuously. The telescope field is displayed to the observer, who identifies his target star and directs the course of the observation in real-time. The 'IUE observatory', thus comprises the ground control centre, where the astronomer views his television monitors, and the optical and electronic instrumentation located in synchronous orbit.

A synchronous orbit has other advantages. Because the Earth subtends an angle of only 17° the unconstrained area of sky is much greater than for low orbits and, as its movement along the ecliptic is at the diurnal rate, the occurrence of occultations is infrequent. Consequently, over large portions of the sky, neither

Table 1 Spacecraft characteristics

Characteristic	Description
Spacecraft mass	312 kg
Scientific instrument mass	122 kg
Apogee motor mass	237 kg

Perigee	25,669 km
Eccentricity	0.24

long exposures nor the observation of variable phenomena need be periodically interrupted. A penalty is that in synchronous orbit observations are normally made in full sunlight so the telescope must be baffled to ensure adequate rejection of stray sunlight and earthlight. Fortunately, sunlight scattered from the Earth's atmosphere contains very little UV energy and so the limiting magnitude of the spectrograph is not appreciably affected by earthlight. The offset guiding system can be influenced, however, and relatively bright guide stars are needed near the Earth's limb.

Fig. 1 IUE spacecraft.

General description of spacecraft

The general arrangement of the IUE spacecraft is shown in Fig. 1. The main body is octagonal in shape, the telescope protrudes from one end and the solar array extends from two opposite sides; in orbit the spacecraft is rotated around the telescope axis to keep the arrays nearly normal to the Sun. The apogee boost motor used to insert the spacecraft into synchronous orbit and the hydrazine auxiliary propulsion system used during the transfer orbit and for manoeuvres throughout the mission are both located in the lower cone assembly.

The telescope and spectrograph are rigidly connected together to form the scientific instrument to which the inertial reference assembly is directly attached to minimise relative displacement. An off-set star tracker within the scientific instrument provides the inertial reference assembly with a reference signal to enable drifts to be corrected. With this arrangement the pointing accuracy of the telescope is a fraction of an arc s.

Other spacecraft systems are described in later sections of this article and the spacecraft characteristics summarised in Table 1.

The scientific instrument

The scientific instrumentation consists of the telescope, the fine error sensors, the echelle spectrographs and the cameras. Each of these units will be discussed in turn.

Telescope and fine error sensor (FES): the telescope has an 0.45 m $f/15$ Cassegrain configuration with a Ritchey-Chrétien figure, giving uniform image shape across the 16 arc min field of view. The characteristics of the optics are summarised in Table 2. Telescope materials were chosen for their light weight, moderate cost, and thermal and optical properties. Beryllium was selected for the primary mirror, and fused silica for the secondary mirror. The telescope tube is aluminium, wrapped in aluminised Mylar thermal insulation; this thermal design produces a nearly constant focus over a wide range of solar aspect angles, and after initial focussing in orbit by movement of the

secondary mirror, no further refocussing should be required. Small corrections to the focus can be made using heaters behind the primary and secondary mirrors.

The forward sunshade is cut at a 43° angle with respect to the optical axis so that the telescope may be pointed anywhere in the sky more than 43° from the Sun. (The 43° angle was selected to permit observations of Venus when it is at greatest elongation.) The forward rim of the sunshade has an additional diffraction edge so that sunlight must be triply diffracted before it can enter the telescope tube. The small amount of diffracted sunlight that enters the telescope tube is further reduced by light baffles inside the tube. The most troublesome source of stray light is the Earth, which may appear at any angle with respect to the telescope axis. The baffles inside the sunshade are angled so that the light is preferentially scattered back out of the sunshade and all off-axis light must suffer at least two scatterings before it can reach a telescope mirror. With this design, stray light from the Earth or the Moon will be of negligible intensity as long as the primary mirror is not directly illuminated, but this can occur if the Earth's limb or the Moon is less than 25° from the optical axis.

Behind the primary mirror there is a shutter which closes automatically if sunlight falls inside the telescope tube. Behind the shutter, the spectrograph entrance apertures are mounted in the focal plane. These apertures are holes drilled in a mirror mounted at 45° to the telescope optical axis and which reflects the telescope field surrounding the apertures into duplicated FES, each of which serves the dual purpose of offset star tracker and field camera. Either is able to scan, in 8 arc s steps, the 16 arc min telescope field, an image of which can be transmitted to the ground for identification by the observer. The FES then measures the coordinates of the target star with respect to the spectrograph entrance apertures so that the spacecraft may be manoeuvred to centre the object in the selected entrance aperture. The FES is then offset to any other star in the field to generate error signals to hold the telescope on target. The limiting magnitude of the FES depends on its mode of operation, but it can track stars as faint as 14th visual mag. Thus any object, regardless of its brightness or nature, may be observed provided its position is known with respect to a nearby guide star.

Echelle spectrographs: behind the 45° aperture plate there are separate short and long wavelength echelle spectrographs, covering the spectral ranges 1,150–1,950 Å and 1,900–3,200 Å respectively. Each spectrograph has a pair of entrance apertures consisting of a hole 3 arc s in diameter and an oval slot 10×20 arc s. Both the larger slots can be closed simultaneously by a shutter, but the smaller holes always remain open. Any particular aperture can be selected by pointing the telescope so that the target image lies in that aperture. The arrangement of the optical components for the short wavelength spectrograph is shown in Fig. 2. Light from the target passes through the aperture plate to the collimator mirror, which is an off-axis paraboloid. The collimated beam is incident on the echelle grating and then diffracted to the spherical grating which acts

Fig. 2 Short wavelength spectrograph.

Table 2 IUE telescope parameters

Image quality	3 arc s
Field of view	16 arc min

both as an order separator and as a focusing element to image the entrance aperture on to the camera. By command, a camera-select mirror may be made to interrupt the beam and divert the image to a redundant camera. Similarly, a plane mirror (labelled the low dispersion mirror in Fig. 2) may be inserted in front of the echelle grating, resulting in a low dispersion spectrum produced by the spherical grating alone. The optical design of the long wavelength spectrograph is the same as the short wavelength spectrograph, except that two plane mirrors inclined at 45° are located behind the long wavelength entrance apertures to direct the incoming light beam to the long wavelength spectrograph and so separate its elements from those of the short wavelength instrument. In the long wavelength spectrograph the spherical grating could produce a second-order spectrum (from ~1,000 to 1,600 Å, which would overlay the 1,900–3,000 Å first-order spectral range), but this is suppressed by a silicon oxide coating on the 45° and collimator mirrors. The optical parameters of the two spectrographs are summarised in Table 3.

The spectrograph section of the scientific instrument also contains a number of light sources. The first of these is a platinum–neon hollow cathode lamp⁸ which is used as a wavelength standard. The lamp is mounted behind the primary mirror and illuminates the spectrograph entrance apertures by a mirror on the back of the Sun shutter so that a platinum spectrum can be recorded to calibrate wavelength as a function of position in the spectrograph image. Tungsten filament and mercury lamps are mounted in front of the cameras in each spectrograph to flood the camera faceplate with light. The former are used in the camera preparation procedure, described below; the latter⁹ can illuminate the cameras with predominantly 2,537 Å radiation, and are used to produce sets of flat-field images at different exposure times in order to derive intensity transfer functions for each picture element (pixel) of the camera format.

The spectrographs are fixed focus and, to minimise thermal effects, their temperature is closely controlled and the optics are mounted using tubes of graphite fibre-reinforced epoxy selected for its low coefficient of thermal expansion.

Spectrograph cameras: in each spectrograph a television camera integrates the two-dimensional echelle spectrum during an exposure and converts the image into video signals suitable for transmission to the ground. There are prime and redundant

cameras in both long and short wavelength spectrographs, all of nominally identical construction. Each camera head contains the electro-optical detector components and some of the electronics, such as the video head-amplifier, which must be close to the television camera tube. The remaining electronics are mounted in the spacecraft.

The basic detector is a UV-to-visible image converter (UVC) coupled to a secondary electron conduction (SEC) television camera which is sensitive to visible light only (Fig. 3). The entrance window of the UVC is magnesium fluoride, transparent to wavelengths above 1,150 Å, and on its inside face is a semi-transparent caesium–tellurium photocathode¹⁰ with a quantum efficiency of 10–15% in the UV but less than 0.01% in the visible. Within the UVC, a high electric field (5 kV across a 1.3 mm gap) accelerates photoelectrons onto a phosphor screen where each produces about 60 photons whose energy peaks in the blue. The screen efficiency is improved by a surface layer of aluminium which reflects backward-emitted photons through

Fig. 4 Typical camera intensity transfer function for image centre (●) and positions of maximum (▲) and minimum sensitivity (×)

the output window; this layer also minimises optical feedback. A matt black coating on the input side of the aluminium reduces halation by suppressing reflection of UV photons which penetrate the photocathode.

The blue image from the UVC is transferred by fibre-optic coupling to the bi-alkali photocathode of the SEC tube. Incorporated in the fibre-optic coupling is a square array of fiducial marks to provide a geometrical reference for the spectral image. The photoelectrons, generated at the photocathode, are accelerated through the electrostatically-focused image section onto the SEC target which consists of a low density porous layer of potassium chloride about 10 μm thick, supported by an aluminium oxide membrane about 50 nm thick, and backed by a thin aluminium signal plate. Some fraction of the energy of each photoelectron is expended in producing several secondary electrons in the potassium chloride which are swept towards the signal plate by a 12V bias across the target leaving an amplified positive charge-image stored on the target, (the process of secondary electron conduction from which the SEC tube¹¹ is named). The gain depends on the accelerating voltage and is about 50 at the highest voltage setting of around 6.1 kV, because of the highly insulating nature of the target an image can be accumulated over many hours and there is no detectable reciprocity failure.

The image is read on completion of exposure. The readout section of the camera tube is similar to that of a standard magnetically-focused vidicon although its operation is somewhat different in that the beam is deflected digitally to scan a raster of 768 × 768 pixels in 37-μm steps across the image. At each pixel, the read beam is pulsed on and discharges the target,

Fig. 3 Camera showing UV to visible image converter and SEC tube

giving rise to an output video pulse corresponding to the positive charge on the target at that pixel. The video signal is digitised into one of 256 discrete levels (DN units) by an 8 bit A/D converter, and these data are telemetered in real-time.

Table 3 IUE spectrograph optics

Optical element	Short wavelength spectrograph	Long wavelength spectrograph
Wavelength range	1,150 to 1,950 Å	1,900 to 3,200 Å
Offset mirrors	None	Two at 45°
Collimator radius	1.89 m	1.89 m
Low dispersion mirror	Plane	Plane
Echelle grating		
frequency	101.9 mm ⁻¹	63.2 mm ⁻¹
blaze angle	45.5°	48.1°
off-normal angle	10.2°	10.2°
Spherical grating		
frequency	313.0 mm ⁻¹	200.0 mm ⁻¹
radius	1.37 m	1.37 m
Camera select mirror	Plane	Plane
High dispersion resolving power*	1.2 × 10 ⁴	1.3 × 10 ⁴
Low dispersion resolution*	6 Å	8 Å

* Based on a predicted point spread function for the entire system (guidance plus optics plus detector) of 120 μm full width at half maximum. Actual resolutions achieved in orbit are discussed in the following paper¹

The cameras are operated by a series of commands issued by the ground station operator through keyboard procedures. Each operational mode has a number of parameters which may be selected by the guest astronomer. The normal image sequence is: PREPARE-EXPOSE-READ. A PREPARE operation is carried out before each EXPOSE to erase all trace of previous images from the target and to provide a reproducible low-noise baseline on which the new image will be superimposed. It consists of preprogrammed sequences of over-exposures to the tungsten floodlamps followed by READ scans. In the EXPOSE mode the UVC and SEC image section high voltages are on (the readout section of the SEC tube is off) and an image may be integrated on the SEC target. Exposure times may be controlled from the ground or by the on-board computer. In the READ mode the image section and the UVC are off and the stored charge image is read from the SEC target as described above.

Camera performance

The response of a camera to UV photons is nonlinear at high signal levels, owing to saturation effects in the storage of charge in the SEC target. The relation between the number of input photoelectrons and the output from the video chain is known as the intensity transfer function (ITF) (Fig. 4). As can be seen, the ITF varies across the image and individual ITF corrections are applied to each of about half a million pixels. The photometric linearisation of the data is an important element of data reduction¹².

Fig. 5 Typical signal-to-r.m.s. noise ratio per resolution element (3 × 3 pixels) as a function of the input to the camera at 2,537 Å.

The ultimate accuracy with which a spectral feature can be measured is set by the quantum statistics of the signal photons incident on the detector but the quantum efficiency of the photocathode reduces this accuracy and it is further degraded by extraneous noise sources which depend on such parameters as SEC target gain, signal level, method of preparation of the target, wavelength and the camera noise level. A typical signal-to-noise characteristic achieved in orbit after photometric correction is shown in Fig. 5.

The spatial resolution of the camera is determined by the combined effects of the UVC and SEC tubes. A typical modulation transfer function (MTF) is shown in Fig. 6; the very rapid drop in MTF at low spatial frequencies is a result of halation.

The dark currents in the UVC and SEC are mainly thermionic in origin and result in a typical background signal of 0.5–1.5 DN per hour of exposure. Images resulting from long exposures usually show a number of small bright spots which vary in time and position; these are probably the result of radioactive disintegrations in the phosphor. Bright spots and streaks can also be caused by interaction of cosmic rays with the input window of the UVC. Aluminium shields not less than 4 mm in thickness surround each camera to provide substantial protection against radiation from the Earth's trapped electron belts which would otherwise produce an unacceptably high background.

Fig. 6 Typical camera modulation transfer function for a, centre of image and b, at half radius (position of worst response).

Geometric distortions produced in the SEC tube amount typically to about 2% of the radial distance and consist of 'pin cushion' distortion produced by the electrostatically-focused image stage, 'S' distortion produced in the magnetically-focused read-out stage, small scale changes due to approximations used in the generation of the dynamic refocus waveform and small intensity-dependent image shifts in the read-out section of the SEC caused by 'beam-pulling' effects.

Spacecraft systems

The major sub-systems necessary to support operation of the scientific instrument are described below. Duplication is used extensively to ensure long term reliability.

Communications: the communications system consists of VHF transponders, S-band transmitters, r.f. power amplifiers and antennas. The characteristics of the VHF and S-band systems are summarised in Table 4. The S-band system is used only for transmission of telemetry data. The two transmitters can be connected to any of the four power amplifier-antenna combinations, but only one transmitter and one power amplifier may be selected at any one time and this will depend on which antenna has the most favourable view of the Earth. The VHF system consists of duplicate transponders and a four-element turnstile antenna and is used for the reception of ground-generated commands, the turn-around transmission of range and range-rate signals for tracking the spacecraft, and also to provide a backup telemetry down-link.

Table 4 Communications systems

	VHF	S-band
Transmitter frequency	136.860 MHz	2249.80 MHz
Power output	6 W	6 W
Modulation	PCM/FSK/AM	PM

Receiver sensitivity	−106 db m	—

Commands initiated by the on-board computer or received directly from the ground are all processed by the two command decoders. Each can process 128 discrete commands and 48, 37-bit serial word commands.

Data handling: the data handling system is composed of the data multiplexer and the on-board computer. The data multiplexer serves as the spacecraft telemetry encoder and as the input data interface between the on-board computer and the rest of the spacecraft. 8-bit words are transferred to a serial data stream which is alternately made available to the ground and to the on-board computer using time sharing techniques. The telemetry bit rate is selectable by ground command from 1.25 to 40 kb s⁻¹. The on-board computer performs all attitude control computations and issues all reaction wheel torquing commands. It performs self-checks, monitors spacecraft performance safety functions, controls camera exposure times, and stores commands.

Stabilisation and control: the stabilisation and control system is used in orbital manoeuvres which include station keeping, pointing, and manoeuvring of the spacecraft. It has three different reference systems: (1) six gas-bearing, pulse-rebalanced, inertial-grade gyroscopes providing 0.01 arc s integrated rate resolution over 600 arc s per s; (2) star trackers (the FESs) in the scientific instrument which use the telescope optics to provide an angular resolution of 0.27 arc s throughout a 16 arc min field-of-view; (3) a two-axis digital Sun sensor which provides angular resolution to 15 arc s over a field-of-view of 64° × 124°. When a bright star is within 9 arc min of the target source, the guidance system uses the FES for position information and gyro system for rate damping. When a guide star is not available, precision-hold depends solely on a well-trimmed gyro reference with low frequency updates from a faint source.

Sequential three-axis manoeuvres from one star to the next use an integrated gyro reference resulting in accumulated errors of <4 arc min. The control system utilises a set of momentum-exchange reaction wheels for attitude control and relies on the hydrazine thrusters for momentum dumping.

Power: power is provided by two solar arrays and a highly efficient distribution and regulating system. During eclipse, and other periods when demand exceeds solar array output, power is provided through a boost regulator from two 6 amp h nickel-cadmium batteries.

Thermal control: the active thermal control system utilises louvres, insulation, heat pipes and heaters. Multi-nodal analysis of a thermal model and solar simulation tests were used to prove the design. The spacecraft may be divided into four sections, each with unique thermal requirements.

(1) The hydrazine bay which contains the hydrazine propulsion system and apogee boost motor and uses a combination of thermal blankets and active heaters.

(2) The main spacecraft compartment which is maintained between 0 °C and +40 °C with the batteries below 30 °C and with the gyros in the inertial reference assembly internally controlled at 57° ± 1 °C. Heat pipes attached to the main equipment platform, together with the louvres, keep gradients to <5 °C.

(3) The telescope, where heaters maintain the primary mirror near 0 °C and the focus mechanism between 0 and +30 °C. The primary mirror is conductively isolated from the telescope structure to reduce axial and circumferential gradients.

(4) The spectrograph, where the cameras are maintained between 0 and +20 °C. Temperature changes and gradients are minimised to prevent thermally induced misalignment. Satisfactory temperature control is obtained by enclosing the spectrograph within an aluminium shield to limit its heat exchange with the main spacecraft compartment and by temperature control of the primary mirror through which most of spectrograph's heat is dissipated.

Ground observatory control systems

Unlike previous unmanned astronomy spacecraft, IUE is operated in real-time by guest observers who generally lack detailed knowledge of the complex spacecraft and ground systems. Ground operating procedures have, therefore, been designed to allow the observer's research programme to be accomplished by selection from a library of modular pre-programmed operating sequences.

Fig. 7 US ground observatory. a, Observing centre; b, image processing centre.

IUE ground control is based on a large real-time computer software system to process telemetry and commands. Relatively complex spacecraft operations are accomplished by calling a series of operating procedures, each designed to accomplish a particular function, such as reading an image from a camera. Procedure execution is controlled by trained telescope operators. A computerised image processing system is then run offline to correct the astronomical images and produce a spectrum in absolute units as a function of wavelength¹³. The processing sequence consists of geometric and photometric correction, wavelength identification, data extraction and system efficiency correction and uses calibration tables derived from periodic analysis of calibration images.

The US ground observatory at GSFC is divided between three separate locations: the ground station, operations control centre, and science operations centre, see Fig. 7. The ground station maintains continuous radio communication with the spacecraft, relays telemetry data to the operations control centre and transmits command messages from the control centre to the spacecraft. The operations control centre contains a Xerox Data Systems (XDS) Sigma 5 computer used for real-time spacecraft operations and image acquisition, an XDS Sigma 9 computer used for image processing and data reduction, and a common disk storage unit. The Sigma 5 computer is operated from a spacecraft control console, consisting of a number of interactive

displays with keyboards used by engineers who continuously monitor the spacecraft performance. The science operations centre houses two experiment display systems (EDS) which are specially designed pseudo-colour image display and analysis consoles, containing their own mini-computers and disk storage. One EDS is used by the observer and telescope operator to conduct real-time observations and the other is used in image processing.

The ESA ground station and control centre is functionally identical with that at GSFC but incorporates a single Sigma 9 computer, with EDS, telemetry, command, and control consoles for operating the spacecraft. From this control centre the ESA- and SRC-sponsored observers use the IUE spacecraft for 8 h each day to conduct their research programmes.

After the IUE's successful launch into an eccentric geosynchronous orbit, and following initial spacecraft checkout, observations were made of a set of high priority targets as an insurance against premature failure of the system. These were followed by the systematic performance evaluation of the various spacecraft and scientific instrument sub-systems, some of which were optimised in orbit. The optical performance of the telescope and spectrograph and the photometric performance of the SEC cameras used as spectrum detectors all seem satisfactory, but the ground data processing system although operational needs further development.

THE IUE was launched from the John F. Kennedy Space Center on 26 January 1978 into an eccentric geosynchronous orbit. The system is described in the previous article. The mission objectives required that the spacecraft be placed in a 24-hour orbit visible continuously from the NASA ground station at Goddard Space Flight Center and for at least 10 h per day from the ESA Villafranca Satellite Tracking Station near Madrid. This coverage allows the Goddard Control Center to control operations for 16 h each day and to monitor health and safety of the spacecraft while the Villafranca Tracking Station operates the satellite for 8 h each day. The orbital elements are summarised in Table 1. The satellite tends to drift slowly in longitude because of slight inaccuracies in the orbital period. However, the ascending node is kept near the longitude indicated in Table 1 by

Fig. 1 Typical variation of electron flux (≥ 1 MeV) measured by the on-board counter. The counter output voltage, V , is related to the electron flux, F (electrons $\text{cm}^{-2} \text{s}^{-1}$), by $V = \log_{10} F - k$ where $k = 3.4$. The right hand scale gives the exposure time in minutes that would give 20% of full scale on the long wavelength redundant camera. This calibration was derived at several counter levels between 1.5 and 2.5 V. The short wavelength prime camera is 1.4 times more sensitive to radiation. a, 31 January–1 February, b, 30–31 January.

occasionally firing hydrazine thrusters. These small orbital adjustments will be required two to three times per year.

After the spacecraft was injected into the synchronous orbit, three-axis attitude control was established and the integrity of the basic spacecraft and scientific instrument systems was verified. At this point a selected set of high priority targets was observed so that some scientific data spanning various research areas would exist in the event of an early failure. An IUE science commissioning team, including project personnel and a few guest observers, had been formed to direct the early scientific checkout, observing, and performance evaluation activities. Each team member was supported by one or more associates so that the team had a large staff of scientists and engineers to assist in the commissioning tasks. The tasks covered three basic phases. (1) Immediately after turn-on, the selected high priority targets were observed to develop observing techniques and to collect some data in each of the broad research categories applicable to IUE. The observations are described in the following papers²⁻⁷ and fall into the categories of hot stars², cool stars³, interstellar medium⁴, X-ray objects⁵, extra-galactic objects⁶, and solar system objects⁷. (2) The scientific instrument and supporting spacecraft equipment were optimised. During this phase the telescope was focused, prime and back-up cameras were selected for each spectrograph, the settings of each prime camera were adjusted to achieve best performance, and the slewing and guiding capabilities of the spacecraft were improved. (3) The photometric properties of the scientific instrument were calibrated against standard stars, and other performance characteristics, such as image quality and spectral resolution, were studied.

At the end of these three phases routine guest observing began on 3 April 1978. The optimisation, evaluation, and calibration tasks were far too large to be fully completed within the available time. However, those items necessary for starting the routine observing phase were finished, and the basic procedures established whereby the scientific commissioning will be completed and maintained by the observatory personnel.

Spacecraft sub-systems

The spacecraft sub-systems whose proper operation are essential to the mission are described in the previous article¹. They include power, thermal, communications, data handling, and attitude control, and all are operating successfully. The power sub-system has performed according to its design since the launch. The solar arrays totally support normal operations over the acceptable range of β -angles (the angle between the telescope axis and the direction to the anti-Sun) from 0 to 135°. As the arrays degrade due to radiation damage the β -angle range for positive power will decrease, and the power system will begin to depend on stored energy from the batteries to maintain operation over all β angles. The batteries and power system

performed normally during the first eclipse period, during which the spacecraft passed through the Earth's shadow every day for about three weeks. Eclipse seasons for IUE, as for the Moon, occur every six months.

The overall thermal performance of the IUE spacecraft has been satisfactory. The only departures from pre-flight predictions are that the power sub-system electronics are running warmer than expected, and there is a larger than anticipated gradient between the two battery packs. There was some initial concern about how the batteries would perform under load with this gradient; however, no problems arose during the first eclipse period. The temperatures throughout the scientific instrument are close to the predictions and the scientific instrument heaters are routinely cycled to keep its thermal conditions within the desired range.

The spacecraft communication and data-handling sub-system has been used in all its various formats and bit rate configurations, and it operates flawlessly. Most operations use a telemetry rate of 20 kbits s^{-1} . The command sub-system is performing properly with hundreds of commands issued to the spacecraft each day to support routine real-time operations. Occasional command-verify anomalies have been observed, but in most cases these have been traced to ground transmitter adjustment errors. Occasional interference is encountered from other NASA satellites during ranging measurements. The primary on-board computer has been in operation since spacecraft turn-on. During the first few weeks several instruction failures were observed which occasionally caused the computer to halt. However, software modifications were installed to detect such conditions and recover automatically without impact on scientific operations. While the primary function of the computer is attitude control, its other functions include timing camera exposures, and monitoring certain spacecraft parameters. As with the other spacecraft systems, a redundant on-board computer is available in case the prime system should fail.

The attitude control sub-system operates satisfactorily in all modes of operation. It controlled nutation and precession while the spacecraft was spinning in the transfer orbit and, after injection into the synchronous orbit, it executed the de-spin and Sun acquisition manoeuvres. Three-axis control was established using the on-board computer, the inertial reference assembly, and the reaction wheels. The initial attitude reference was obtained by measuring the solar position with fine Sun sensors in pitch and roll and the approximate Earth position with a panoramic attitude sensor in yaw. The spacecraft was then slewed to point the telescope toward the North Ecliptic Pole, where a star field was identified using the telescope and star tracker. Manoeuvres to new positions are performed, one axis at a time, by inserting in the on-board computer new gyro references relative to the known spacecraft orientation. Reaction wheels slew the spacecraft, and hydrazine reaction jets are fired once or twice daily to reduce wheel momentum that accumulates due to disturbance torques on the spacecraft. Typical pointing errors after large angle slews have been 1–2 arc min, which is well within the 16 arc-min field of the telescope. The star tracker in the scientific instrument can identify and guide on stars brighter than 14 mag. Using the star tracker for guidance, pointing accuracies ~ 0.2 arc s have been achieved. On the rare occasions when there is no suitable guide star in the field, the gyro drift rates may be nulled while the tracker is guiding on a nearby star and then the gyros may be

used for inertial guidance with random drifts ~ 3 arc s per h. If moving targets are to be observed, the gyro rates can be adjusted to track the target's motion.

Optical performance

Measurements of telescope image quality before launch indicated that the ratio of transmission between the small spectrograph entrance aperture (3 arc s) and the large spectrograph entrance aperture (10×20 arc s) was 0.65 at 20°C , 0.60 at 5°C , and 0.55 at -10°C . Because of air turbulence and the angular diameter of the laboratory source, these measurements were considered to be lower limits of achievable performance.

Thermal conditions have been adjusted in orbit and are being controlled actively to maintain a nominal primary mirror temperature of -3°C . This should allow pointing to any object outside the 43° Sun avoidance cone without significant changes to telescope focus. After refocusing the telescope in orbit, spectrograms of the same star obtained using the large and small apertures in the short wavelength spectrograph have indicated small aperture transmissions of up to 70%. Spectra of stellar images in the large aperture are ~ 5 arc s full width at half maximum, perpendicular to dispersion.

Sources of scattered light in the telescope may be divided into three categories: the Sun; Earth and Moon; and bright stars. The IUE telescope baffles (see ref. 1) were designed to eliminate sunlight over the region of sky outside the 43° half-angle Sun avoidance cone. No evidence of scattered sunlight has been observed at angles of 50° or more from the Sun. At angles between 45 and 50° , stray sunlight is barely detectable in the star trackers. There are no restrictions on observing near the Earth or Moon, but scattered light may affect the operation of the star trackers. Observations of stars with no evidence of scattered light contamination have been made within 25° of the Moon and within 25° of the Earth's limb. The practical limit has not yet been fully determined, but when the Earth is within the 16 arc min field-of-view, the star tracker output is saturated in every operational mode. Observations of Jupiter and its satellites have shown that 6th mag objects can be observed and tracked within 90 arc s of a -1.7 mag object. This performance would scale to tracking a 14th mag object at 90 arc s from a 6.3 mag object. It is also important to know how severely the spectrum of an object can be contaminated by scattered light from a bright star located close to it. Tests on η UMa show attenuations of 10 stellar magnitudes when the star is 10 arc s from the small entrance aperture of the long wavelength spectrograph and 12 stellar magnitudes at 20 arc s.

The resolutions of the long wavelength and short wavelength spectrographs have been determined from spectra of the Pt–Ne

hollow cathode lamp that is used on-board for wavelength calibration. At high dispersion in the short wavelength spectrograph, the full width at half maximum (FWHM) of a spectral line from the Pt–Ne lamp is $0.085 \text{ \AA}$ at $1,150 \text{ \AA}$, and it increases linearly with wavelength to $0.19 \text{ \AA}$ at $2,100 \text{ \AA}$. In the long wavelength spectrograph, $\text{FWHM} = 0.20 \pm 0.01 \text{ \AA}$, constant with wavelength. The data for the short wavelength spectrograph correspond to a resolving power, $R = \lambda/\text{FWHM} \approx 1.2 \times 10^4$, as was expected. The data for the long wavelength spectrograph give resolving powers that vary from 1.0×10^4 to 1.5×10^4 over the wavelength range rather than the approximately constant value of 1.3×10^4 that was expected. The reason for this is not yet understood. The spectral resolution measured from Pt–Ne spectra in the low dispersion modes is $\leq 7 \text{ \AA}$ in the short wavelength spectrograph and $\leq 8 \text{ \AA}$ in the long wavelength spectrograph. These results are upper limits because all features of the Pt–Ne spectrum observed at low dispersion are, to some extent, blends of several lines.

The on-board Pt–Ne lamp⁸ serves two purposes. First, it defines the spectral format to guide the extraction of data from the spectrum and its local background; this is clearly a more intricate process in the high dispersion mode with its 2-dimensional format. Second, it assigns a wavelength to each data point of an extracted spectrum. The procedure involves two steps. First, the emission line spectrum of the lamp is obtained, and the positions of the spectral lines on that image are found using a cross-correlation technique. In the case of the high dispersion spectra ~ 200 spectral lines are located, while in the case of low dispersion spectra the number is ~ 15 – 20 . Second, a multivariable regression analysis is performed to relate the sample s and line l positions to their wavelength λ and order numbers m . The equations of condition are given below for high dispersion:

$$s = a_0 + a_1 m \lambda + a_2 (m \lambda)^2 + a_3 m + a_4 \lambda + a_5 m \lambda^2 + a_6 m^2 \lambda$$

$$l = b_0 + b_1 m \lambda + b_2 (m \lambda)^2 + b_3 m + b_4 \lambda + b_5 m \lambda^2 + b_6 m^2 \lambda$$

and for low dispersion

$$s = a_0 + a_1 \lambda \quad l = b_0 + b_1 \lambda$$

These dispersion constants are then used to define the spectral format of the target spectrum. The errors in this procedure are assessed in Table 2, which shows that the largest uncertainty in assigned wavelengths arises in transferring the dispersion constants derived from a Pt–Ne spectrum to the image of a stellar spectrum. These errors can be removed by identifying a feature in the astronomical source and applying an appropriate correction.

Table 2 Sources of error in wavelengths

Source	High dispersion	Low dispersion
Error in laboratory wavelength	$< 0.004 \text{ \AA}$	$< 1 \text{ \AA}$
Error in measured positions of spectral lines	$< 0.07 \text{ \AA}$	$2 \text{ \AA}$
Inadequacy of dispersion formulae to represent spectral format	$< 0.07 \text{ \AA}$	$< 2 \text{ \AA}$
Error in transferring dispersion relations to target spectra	$0.2 \text{ \AA}$	$6 \text{ \AA}$

Camera performance

Before launch an extensive programme was undertaken to investigate the effect on camera performance of the settings of the camera-tube and deflection-coil operating parameters⁹. This programme resulted in a set of values for the commandable voltages that was used immediately after launch to observe the high priority targets. After the high priority observing period, time was allocated to check the commandable camera settings, using the performance before launch as a baseline. In addition, the post-launch check on the operating parameters was extended to include the implementation of a new target preparation sequence, called SPREP, which had been developed during additional laboratory testing of the flight spare cameras.

Table 3 Camera performance

Camera	Photometrically corrected 40% image				Random noise on pedestal			Preparation sequence
	Mean S/N* (Single pixel)	Min. S/N (Single pixel)	Mean S/N (3 × 3 pixels)	Photometric† stability	Mean σ‡ (Single pixel)	Peak σ (Single pixel)	Mean σ (3 × 3 pixels)	
Long wavelength redundant	10.0	5.8	21.2	±7%	3.0 DN	7.9 DN	1.1 DN	TPREP: ground calibration
	13.4	8.0	29.0	±2.5	1.4	2.7	0.4	SPREP: after re-optimisation
	8.7	5.5	19.4	±5.5	2.9	6.0	1.0	SPREP: in-orbit ITF
	7.8	3.5	19.2	±7.5	2.7	5.7	0.9	FPREP: after re-optimisation
Short wavelength prime	12.2	4.0	30.2	±13.5	1.6	2.8	0.7	TPREP: ground calibration
	10.5	6.5	23.1	±2.5	1.4	2.9	0.5	SPREP: after re-optimisation
	10.9	6.6	25.0	±3.2	1.7	3.6	0.6	SPREP: in-orbit ITF
	11.1	6.0	25.0	±5	1.3	2.2	0.6	FPREP: after re-optimisation

All results refer to the low gain setting of the head amplifier with the SEC tube at maximum gain.
* The mean signal-to-noise (S/N) ratio is averaged over the whole target area for both individual pixels and for 3 × 3 pixel blocks. The minimum S/N ratio is the mean over a block of 24 × 24 pixels in the area of worst noise.
† The photometric stability represents the peak-to-peak spread in signal level after photometric correction has been performed.
‡ The mean standard deviation (σ) is averaged over the whole target area for both individual pixels and for 3 × 3 pixel blocks. The peak standard deviation is the mean over a block of 24 × 24 pixels in the area of worst noise performance.

SPREP has now replaced the original preparation sequence, TPREP, which was used during high priority observing. Further images were obtained to serve as a new baseline for measuring long term drifts in camera performance. Two other target preparation sequences, also initially developed in laboratory testing, have been implemented. These are FPREP, a fast preparation sequence designed for use when speed of operation is important and some degradation in image quality can be tolerated, and XPREP, which can be used to remove residual effects of over-exposed images.

The function of the preparation sequences is to remove all trace of previous images and to leave the target with a uniform low-level low-noise pedestal. Target preparation involves a saturation exposure of the camera, using tungsten floodlamps, and read out of the charge, followed in the case of TPREP and SPREP by a lower level flood exposure and subsequent read. The original preparation sequence, TPREP, has the disadvantage that beam pulling effects can lead to small scale instabilities in the action of the read beam, particularly when reading out the saturated exposure of the preparation sequence. These beam instabilities result in patches of increased noise and poor photometric stability. The new sequence, SPREP, gives significant improvements in photometric stability and considerably reduced noise on low-level signals. The improvements are

achieved principally by scanning the target with a defocused beam and with carefully chosen alignment settings, permitting a much more stable scanning action. Other improvements in noise performance are obtained by making the second floodlamp exposure at a lower gain setting, thus reducing the effect of photon noise, and by increasing the level of this exposure from 20% of saturation to 50%, at which level the random noise on the pedestal has been shown empirically to pass through a minimum value.

Table 3 lists the camera performance before and after reoptimisation. The performance using SPREP is significantly better than that for TPREP. The photometric stability is considerably improved, the signal-to-noise ratio in the worst areas has been improved, and the random noise on the pedestal has been reduced, particularly in the case of the long wavelength redundant camera. Also shown in Table 3 is the camera performance derived from the photometric calibration images taken shortly after the end of the reoptimisation programme. The performance of the short wavelength prime camera is comparable with that determined from the evaluation images taken as part of the reoptimisation work. However, in the case of the long wavelength redundant camera the performance seems to have degraded. The reason is not yet fully understood and more analysis remains to be completed. The apparent change may be a result of temperature transitions in the region of the detector or associated electronics which could cause a slight shift in the position of individual pixels on the scanning raster and hinder the removal of fixed pattern noise.

FPREP, the fast target preparation sequence, is achieved using a single floodlamp exposure and carrying out the read operations at a scanning rate of 320,000 pixels s⁻¹, which is 64 times the speed of the fastest scanning rate used in other modes and is considerably faster than the response time of the line deflection digital-to-analogue converter. The beam is not pulsed as it is in normal operation, but is held on continuously during the scan and the staircase waveform applied to the deflection coil is smoothed into a slope on which are superimposed spikes resulting from 'glitches' in the digital-to-analogue converter. These spikes give rise to a series of vertical bars, typically about 10% of saturation, superimposed on the image and degrading the quality of the data. It had been thought that these bars would not be stable with time, preventing their removal by means of photometric correction, and Table 4 shows that FPREP is significantly inferior to SPREP in the case of the long wavelength redundant camera, though still quite adequate for its intended use. The performance of FPREP for the short wavelength prime camera compares favourably with that using SPREP. It remains to be seen whether the bars are stable in the long term.

XPREP, which is used to remove the residual components of highly over-exposed images, is similar to FPREP, except that the floodlamp exposure level is four times larger, driving the

Fig. 3 Contrast-enhanced but otherwise unprocessed low-dispersion short wavelength spectrum of the faint ($B \sim 14$ mag) extragalactic object B2 1101+38 exposed for 4 h. The geocoronal Ly α emission fills the 10×20 arc s aperture and can be distinguished from the narrower object spectrum. There is no sign of background from other atmospheric emissions either in this or the long wavelength spectrum. The numerous bright spots are generated in the detector. The comet-like image near top right is a cosmic-ray induced event occurring in the detector optical components.

Fig. 4 Photographic representations of a raw camera image showing two low resolution short wavelength spectra of θ^2 A Orionis (O9.5 Vp, $V = 5.07$). The upper spectrum was exposed for 1 s through the large aperture and the lower spectrum was exposed for 4 s through the small aperture. The spectra extend from $\sim 2,000$ to $1,150$ Å. The strong interstellar Ly α absorption line at $1,216$ Å is clearly seen at the short wavelength end of each spectrum.

target well into saturation and completely obliterating any residual images. XPREP is normally followed by SPREP in order to obtain a reproducible low-noise pedestal. It has been used on both the long and short wavelength cameras following exposures containing spectral lines that were over-exposed by factors of up to 1,000. Initial results show that all traces of residual image are removed, while control exposures using SPREP only show residual signal levels of several per cent in line images that were over-exposed by factors of $\sim 1,000$.

The efficiency of IUE depends on the amount of overhead time associated with each exposure. In addition to the times for slewing and for target acquisition there are overheads associated with the operation of the cameras. As shown in Table 4 these fall into the categories of camera hardware overheads and ground control computer overheads. Considerable improvements were made to the latter during commissioning and further improvements are expected in the procedures by which the computer controls camera operations. Table 4 shows overheads for the two most commonly used telemetry rates, 20 and 40 kbits s^{-1} . It is often possible to hide the overhead associated with SPREP and READ by performing them during a long exposure in the other spectrograph; SPREP may also be carried out during a slew.

Background corrections

There are several contributors to the background which are apparent in camera images. The first of these is the null pedestal discussed in the previous section. This pedestal is a zero offset, typically amounting to 15% of saturation, that must be sub-

Table 4 Overhead time associated with camera operations

tracted from each image. Although there is in principle a time-dependent internal tube noise due to thermal effects and to phenomena such as phosphorescence in the image converter, in practice the tube background appears to be negligible for exposures as long as 5.5 h, which is the longest integration time attempted so far.

During the passage of the satellite through the Earth's outer belt of trapped electrons there is often a significant background level in the data due to Cerenkov radiation in the input window. There is apparently no effect on the stored image in the SEC tube when the camera is in the STANDBY or READ modes. A silicon diode ionisation counter on board the spacecraft serves as a real time monitor of the flux of electrons ≥ 1 Mev, which are those expected to penetrate the radiation shielding and produce Cerenkov radiation. Figure 1 shows the variation of the output of the counter during parts of two typical orbits. The main maximum always occurs before perigee as the satellite passes just above the peak of the outer belt on its way south. The second maximum occurs as the satellite passes north at a greater altitude. The result of the in-orbit calibration of the response of the cameras to this radiation is also shown in Fig. 1. Using this calibration and the real time output from the radiation counter the observer can arrange to terminate his exposure at a suitable background level.

Figure 2 shows the statistics of the day-to-day variation in maximum radiation flux. From this figure it will be seen that for $\sim 40\%$ of the time exposures of over 2 h are possible during the passage through the belt. During the remaining 60% of the orbits, there will be restrictions on the maximum exposure time for periods between 2 and 8 hours duration. The radiation level in the belt is expected to increase as the peak of solar activity is approached.

Fig. 5 Photographic representation of a raw camera image showing a high resolution short wavelength spectrum of θ^2 A Orionis. The exposure was for 5 min through the small aperture. Echelle orders in the lower left portion of the figure provide wavelength coverage to $\sim 2,100$ Å while orders in the upper right provide wavelengths down to $\sim 1,150$ Å. The broad interstellar Ly α absorption line at $1,216$ Å nearly eliminates two complete echelle orders. Numerous narrow interstellar lines can be seen but they should not be confused with the rectangular pattern of fiducial marks.

Fig. 6 A selection of low dispersion short wavelength spectra obtained by IUE during the commissioning period. Some of the strongest lines are identified. *a*, 3C273; *b*, NGC7027; *c*, η Car; *d*, BD+75°325.

The only detectable sky background source is geocoronal Ly α emission. This is evident in the example shown in Figure 3, which is a contrast-enhanced, low dispersion spectrum taken with the short wavelength redundant camera of the faint ($B \sim 14$ mag) extragalactic object B2 1101+38 exposed for 4 hours during the commissioning phase. Here the geocoronal Ly α emission, which fills the 10×20 arc s entrance aperture, can be distinguished easily from the object spectrum, which appears as a point source. There is no sign of background from atmospheric continuum emission or from other line emissions, such as the O I multiplet near λ 1304 or [O I] λ 1356, which are known to peak far below the satellite altitude. There are some bright spots generated in the detectors themselves; residual optical 'hot spots' may fluoresce in the phosphor of the UV converter following the flooding of the preparation procedure, and phosphor radioactive decay spots and internal ion events appear occasionally. Finally, cosmic-ray induced events, which exhibit a comet-like appearance, may occur in the detector optical components. These are distinct from the diffuse Cerenkov radiation background caused by trapped radiation. Cosmic rays usually produce small clusters of saturated pixels that must be ignored in analysis of the data. Clearly, it is important to use the basic pictorial data to distinguish real from spurious lines by verifying that any apparent feature is the same width as the actual spectral image.

Photometric performance

Figures 4 and 5 show representative raw images obtained with the short wavelength prime camera at low and high dispersion. These are photographic representations of the original camera images and are a standard data reduction product. For both figures the object is θ^2 A Orionis (O9.5 Vp, $V = 5.07$), a bright early type star in the vicinity of the Orion nebula. For the low

resolution exposure in Fig. 4, spectra were obtained through both entrance apertures and the resultant spectra extend from $\sim 2,000$ to $1,150$ Å. At the short wavelength end the interstellar Ly α line at $1,216$ Å is clearly seen. For the high dispersion spectrum in Fig. 5 the small aperture was used. The interstellar Ly α line nearly eliminates two complete echelle orders and numerous narrow interstellar lines are also clearly visible but should not be confused with the rectangular pattern of fiducial marks which is used for the geometrical correction of the raw images.

Several sample spectra, which have been extracted from camera images similar to those just discussed, are shown in Figs 6 and 7. Figure 6 contains four low resolution spectra obtained with the short wavelength camera during the commissioning period. These spectra illustrate the great versatility of the instrument in observing a diversity of astronomical objects. A dynamic range of 18 mag in the incident flux can be covered by using appropriate exposure times and dispersion mode. In addition to the samples shown here, IUE has obtained UV spectra of cool stars, other extragalactic objects, standard stars, and Solar-System objects, including Mars, Jupiter, Uranus, and the Moon. Spectra ranging from a pure emission line object in the planetary nebula NGC7027 to a smooth continuum source in the hot star BD+75°325 are shown in Fig. 6. The presence of some noise due to quantum statistics and residual system noise is evident,

Fig. 7 A selection of high dispersion stellar spectra from order 106 of the short wavelength echelle spectrograph. The two strong absorption lines of O I and Si II are primarily interstellar. The glitch on the left in HD153919 is produced by one of the camera fiducial marks which are about 3 pixels wide. *a*, η UMa; *b*, ζ Oph; *c*, HD153919; *d*, HD93521.

Fig. 8 Inverse absolute sensitivity curves for the short wavelength cameras in low dispersion. Multiplication of the indicated values by the linearised flux numbers obtained from the COMPARE data extraction program and division by the exposure time yields absolute fluxes for continuum sources in $\text{erg cm}^{-2} \text{s}^{-1} \text{\AA}^{-1}$. The curves are for the short wavelength redundant camera as used during the high priority observations and for the re-optimised short wavelength prime camera as it is now being used for routine observing. As the data reduction system scales fluxes differently for the two cameras, these curves should not be used directly for estimating exposure times. The real sensitivity difference between the prime and redundant cameras is only about a factor of two. *a*, SWR(4); *b*, SWP(3) reoptimised

particularly in BD +75°325. The emission at 1,216 Å is typically present in long exposures at low dispersion and is due to resonant scattering of solar Ly α in the geocorona as discussed earlier. Note that in the quasar 3C273 the intrinsic Ly α and C IV 1,550 Å emissions are shifted longwards by the redshift $z = 0.158$.

Part of order number 106 from the short wavelength echelle spectra of four stars is shown in Fig. 7. Strong interstellar lines of O I 1,302.17 Å and Si II 1,304.37 Å are evident. Some variation in line position exists, because wavelengths are not corrected for velocities external to the spacecraft and because η UMa and HD153919 were observed in the large aperture, where pointing uncertainties cause wavelength errors. In η UMa, note the stellar features that are broad and shallow, in contrast to the sharp interstellar lines. The background used to find the net response in Fig. 7 was measured between the orders, where there is some residual due to lack of complete separation of the echelle orders at these wavelengths. Consequently, the cores of the interstellar lines tend to lie below zero. Improvements in the data processing system will be needed to correct this.

There are at least seven sources of noise in the IUE data: (1) quantum noise in the detected photoelectrons; (2) noise in the individual intensity transfer function (ITF) curves used to linearise the raw data values and reduce them to flux units; (3) inaccuracies in aligning the stellar images with the flat field images of the ITF sequences, so that each pixel uses the exact ITF curve intended; (4) random system noise in the tube readout and telemetry; (5) pseudo-periodic noise from other spacecraft subsystems; (6) noise in the pedestal level, which is the zero signal charge on the target after the camera preparation sequence, and (7) radiation background. The radiation background is discussed above and can be neglected for the short exposures described here. Care must be exercised to subtract in a smooth way any backgrounds present in the gross signal; otherwise, additional noise can be introduced by the data reduction. Table 5 lists some one- σ noise levels per sample point in IUE gross extracted spectra, where σ_{gross} includes noise from sources 1-6. The values of σ_0 are the quantum noise expected from the number of photoelectrons required to produce a net signal of 90% of saturation. For the spectrum of η UMa obtained with the long wavelength redundant camera, the measured noise approaches the theoretical value. In the other cameras, the measured noise is about twice the theoretical limit.

The low resolution IUE data best define the photometric reproducibility of the IUE system, because the background can

be measured reliably on either side of the spectrum. Studies of the photometric stability were therefore made by taking low dispersion spectra of the same star (HD50753, B3 IV, $V = 6.7$ mag) at periodic intervals in the large slot of each spectrograph. These data were obtained from 21 March-15 May 1978, and indicate a change in the sensitivity of the system. Over the full 55 days, the data showed decreases in sensitivity of 5% at 1,400 Å and 12% at 1,700 Å (taken with the short wavelength prime camera) and decreases of 5% at 2,150 Å and 9% at 2,750 Å (taken with the long wavelength redundant camera). The reasons for these changes are not yet understood and they will continue to be investigated as part of an overall programme to maintain a photometrically calibrated system.

Preliminary absolute sensitivity curves for low resolution IUE spectra have been obtained by observing hot stars with absolute energy distributions established from previous satellite and rocket observations. This procedure was preferred to a pre-launch calibration, as major efforts have been undertaken in the UV to calibrate existing satellite data¹⁰. The only extensive set of UV flux measurements available that covers the entire wavelength range spanned by IUE is the absolute OAO 2 spectrophotometry^{11,12}. Therefore, we have chosen to relate the preliminary IUE sensitivity curves to the absolute spectrophotometry on the OAO 2 system. Figures 8 and 9 show preliminary inverse sensitivity curves for all four cameras. The curves for the long wavelength redundant and short wavelength prime cameras apply to their re-optimised performance. The curves for the long wavelength prime and short wavelength redundant cameras are as they were used during the high priority phase of the scientific commissioning. The quantity plotted, S_{λ}^{-1} ($\text{erg cm}^{-2} \text{\AA}^{-1} \text{FN}^{-1}$), and the absolute flux, F_{λ} ($\text{erg cm}^{-2} \text{\AA}^{-1} \text{s}^{-1}$), are related by

$$F_{\lambda} = S_{\lambda}^{-1} \frac{(\text{FN})}{t}$$

where t is the exposure time in seconds and the IUE flux number (FN) is the linearised extracted net spectrum. Because of the details of the linearisation that produces FN, the sensitivity curves do not represent actual differences between cameras. The curves plotted are for large aperture exposures and a 10 pixel high spectral extraction with the program COMPARE. For small aperture exposures, where the light loss will depend on the telescope focus and the object positioning these curves can only be used in the relative sense. The curves are based on short exposures (~ 0.6 -2 s) of μ Columbae (HD38666, $V = 5.17$) timed with the aperture select mechanism in order to avoid uncertainties associated with the rise and fall times of the camera high voltage. The timing uncertainty associated with this

Fig. 9 As for Fig. 8 but for the long wavelength cameras *a*, LWP(1), *b*, LWR(2) reoptimised.

mechanism may approach 10% for the shortest exposures. The sensitivity curves of Figs 8 and 9 imply short and long wavelength limits at about 1,150 and 3,200 Å, respectively. These sensitivity curves were obtained using preliminary intensity transfer curves to linearise the raw camera responses and a data extraction system that requires revisions. They should permit the transformation of IUE data into the OAO 2 spectrophotometric system with a relative accuracy of ~10%. However, the final result is also subject to the additional uncertainties of the OAO 2 absolute calibration, which seems to be accurate to about $\pm 5\%$ for $\lambda > 1,800$ Å and $\pm 20\%$ for $\lambda < 1,800$ Å. Figure 10 shows the result of using the derived short wavelength redundant camera calibration to compute a stellar flux distribution. The bump near 1,500 Å is located just where the OAO 2 flux distributions lie furthest above the measurements of the TD-1 satellite and other experiments¹⁰.

Because of its importance, a completely independent calibration, based on the same principles as above but using the TD-1 (S2/68) absolute fluxes as standard, was carried out during the commissioning phase. This is described by Boksenberg *et al.*⁶, and shows differences from that above (for example, it does not produce a bump near 1,500 Å) and further work is needed to establish the best sensitivity curves for general IUE use. In the work described in the following papers, both of these early calibrations have been used, that based on TD-1 for the interstellar⁴ and extragalactic⁶ work, and that based on OAO 2 for the rest^{2,3,5,7}.

Data reduction

Figure 11 shows the flow of the various types of images through the major steps of the data reduction system. Wavelength calibration lamp images are the emission line spectra from the on-board Pt-Ne source. Sequences of flat field images allow the nonlinear intensity transfer function (ITF) to be measured for each pixel in the image field. The standard star images are used to determine the absolute instrumental sensitivity by comparison with previous rocket and satellite spectra.

The first manipulation performed on each image is a geometrical transformation to make each pixel in each image

Fig. 10 a, The IUE spectral response for HZ43 produced by the image processing system after ITF correction. b, The absolute flux estimate for the object after application of the preliminary absolute calibration.

Fig. 11 The flow of images through the IUE spectral image processing system, showing the major image processing and data reduction tasks to be performed on each type of image.

refer to the same point in the focal plane at the camera faceplate. This removes the distortion inherent in the electron optics of the SEC tube, and hence the spectral orders are straightened out so that simpler fitting functions can be used to find the orders. However, in doing this transformation the data have been resampled, which results in some smoothing, each pixel in the transformed image being the linearly weighted average of the four adjacent pixels in the raw image. The next step is the photometric or ITF correction, which involves each point in the 768×768 pixel image being transformed with its own ITF curve. There are 12 levels of exposure in the ITF tables, with multiple images averaged together at each exposure level to reduce noise. Each pixel of the image being reduced is corrected by interpolation in its own 12-point table. The result is an image that is related linearly to the input flux on the camera, but has had no wavelength-dependent sensitivity corrections applied to it.

The next step is to extract the spectral data from the images. The location of the spectrum must be determined and this is obtained from known emission lines in the spectrum of the Pt-Ne calibration lamp, whose position, order number, and wavelength are fitted to the dispersion equations given above. When spectra are taken through the large entrance aperture, the wavelength scale derived from Pt-Ne calibration images obtained through the small aperture must be shifted linearly by about 30 pixels. In this case, the zero point of the resulting wavelengths may be slightly in error due to uncertainties in the exact centering of the target image within the 10×20 arc aperture. After wavelengths have been assigned, the extraction of the spectrum is accomplished by passing one pseudo slit with a height of 5 diagonal pixels along the orders and another pseudo slit 1 diagonal pixel high between the orders. The inter-order background is smoothed and subtracted from the spectrum. This net spectrum must still be corrected for the system sensitivity. In high dispersion, a 'ripple correction' is applied to remove the effect of the echelle blaze. The data are then multiplied by the system sensitivity curves derived from standard stars.

Several problems remain in the data reduction as of May 1978, one of the major ones being the proper separation of the high dispersion orders. In the extraction of the high dispersion spectrum the smoothed interorder background is subtracted. This is adequate for the orders that are far enough apart for the inter-order background to be a true measure of the local background. However, as the order separation decreases at the shorter wavelengths, the inter-order background becomes an over-correction in both spectrographs. A major complication is that a variation of step size caused by the dynamic refocus voltage in the cameras makes the echelle orders deviate from straight lines, even in a geometrically corrected image. Therefore, in the refocus regions the pseudo slits that track the spectrum and the interorder background tend to lose or gain

signal, respectively. Thus, a small dip of typically 10% in an extracted spectrum becomes an even larger error when the anomalously high inter-order background is subtracted. Clearly, much more work is needed on this and other outstanding data reduction problems before an adequate image processing system is available for guest observers.

IUE observatory operations

The IUE observatory consists of the flight system plus the ground system. The flight system includes the spacecraft, the telescope, and the scientific instrumentation. The ground system includes the NASA IUE operations control centre at Greenbelt and the ESA's Villafranca satellite tracking station. The IUE observatory is designed to make maximum use of the continuous contact offered by the geosynchronous orbit. Guest observers are able to come to the observatory's science operations centres and actively participate in the real time control of their observations. In addition, the guest observer may take advantage of observing opportunities as they arise. Experienced resident astronomers and other observatory staff members assist the guest observer by providing advice on program planning, instrument operation, and data processing techniques. A guest observer usually arrives at the appropriate ground station a few days early to become familiar with the operations and data processing systems and to plan the final details of the observing program in consultation with resident astronomers.

The real time operations interface between the guest observer and the IUE is an interactive control and display terminal. This is manned by a telescope operator who is a specialist in spacecraft manoeuvring, target acquisition and instrument operation. The guest observer also sits at the display, and in consultation with the resident astronomer and telescope operator, directs critical aspects of the observation, including target acquisition, instrument operation, and data evaluation. The

interactive display provides the observer with all the information needed to plan slews, and also presents the field of view of the telescope to allow target identification. A quick-look spectrum is displayed as soon as the image is transmitted to the ground, and this allows the observer to evaluate the data quality and decide whether to repeat the observation or proceed to the next. The reduced data are available in the form of photographic reproductions of the raw and corrected images, verification plots of intensity versus wavelength, and magnetic data tapes. These materials are normally delivered to the observer 1 or 2 days after the observation.

Observers are given exclusive rights to their observations for 6 months after receipt of their data. The only exception to this rule is the right of an ESA observer to request full data on a duplicate target observed during a previous ESA shift. After 6 months, the data are deposited in the national space science data centre at Goddard Space Flight Center and in the data centres of the UK and the ESA. These data are available on request. Observers will be encouraged to use the data centres, rather than needlessly repeat observations; they may also find it advantageous to collaborate with other astronomers having similar observing programmes so that their combined observing time can be used to the greatest advantage.

During the commissioning phase of IUE observations were made of a selection of hot stars: the white dwarf HZ43, the hot subdwarf BD + 75°325, the nucleus of the planetary nebula NGC6826, the dwarf nova SS Cygni, and the peculiar object η Carinae. The observations were made in the low dispersion mode and the data have been reduced using a preliminary calibration. The results are presented and discussed for each object.

THE IUE now provides the opportunity for major advances in the study of hot stars at UV wavelengths. The ability to detect faint sources now permits: (1) the study of hot, subluminescent stars which as a group represent the avenues to the endpoints of evolution for the great majority of stars; (2) the study of hot, massive stars in external galaxies (the Magellanic Clouds); and (3) the study of hot stars (and their surroundings) which are heavily reddened by the interstellar medium. Another basis for this opportunity is the provision for complete spectral coverage from 1,150 to 3,200 Å, which permits: (1) a detailed study of a

Fig. 1 Relative flux distribution of HZ43. Two abscissae are given, below, data point number of the spectrum extracted from the image; and above, the wavelength. The break in the spectrum near 1,230 Å is due to a rescan

spectral region usually inaccessible to Copernicus, roughly 1,450–1,800 Å, which contains several lines (for example, C IV λλ 1548, 1550; He II λ 1640; N IV λ 1719) which are very useful diagnostics of the physical conditions in hot stars; and (2) the study of flux distributions of hot stars over a wavelength interval wide enough to distinguish differences. Finally, the imaging capability of IUE yields an efficiency and, potentially, a freedom from time-dependent errors associated with scanning spectrometers. This capability permits programmes of study based on repeated observations of variable hot stars, such as the Ap stars, binaries and pulsating stars.

During the commissioning period of IUE a sample of hot stars were chosen for observation. The main criterion for selection was that they should represent classes of hot stars deserving thorough study but, by virtue of their faintness, were previously inaccessible to UV spectroscopy. Because of the short time allotted for these observations it was decided to concentrate on the hot, subluminescent stars but to try to sample as many types of this class as possible. In addition, the object η Car was selected because of its peculiarity and heavy reddening. All spectra were obtained at low dispersion and have a nominal resolution of 6 Å. Table 1 lists the stars observed.

The emphasis of the work described here was to assess the usefulness of IUE low-dispersion spectra to conduct studies of hot stars. However, hot stars were observed at high dispersion during the commissioning period as parts of investigations concerning X-ray sources¹ and the interstellar medium².

Observations and reductions

Table 2 lists some of the observational data: the object, the image number, date of observation (day number of year 1978), the entrance aperture (small or large), the exposure time and comments about the quality of the spectrum. Most of the latter are based on an inspection of photographic reconstructions of the raw spectral data which allow qualitative assessments of such characteristics as general exposure level, system focus, systematic noise, and effects of particle radiation. The exposure levels of most spectra seem to be near optimum. In the short wavelength spectrograph, the small decline in system sensitivity towards

shorter wavelengths is compensated for by the characteristic increase in flux of the hot, unreddened stars under study here. Hence, one well-exposed spectrum is useful for the full spectral range, from ~1,150 to 2,100 Å. The same generalisation holds true to a lesser extent for the long wavelength spectrograph covering the spectral region from 2,100 to 3,300 Å. The spectrograms generally show a low background level, and except for SWP 1141, which was obtained when the telescope was pointed near the Earth's limb, geocoronal Lyα is not present.

Fig. 3 Relative flux distribution of NGC6826

The spectral images were reduced by a process, still under development, described in the preceding article³. Any error in the zero-point of the wavelength scale was then removed by assigning the laboratory wavelength to an identifiable feature, such as Lyα. This procedure was possible for all spectrograms except for those of η Car where no features were readily identifiable. The net spectrum was converted to absolute flux units with the preliminary system sensitivity functions derived from standard star observations (described in ref. 3). This sensitivity function tends to produce a swell near 1,500 Å and it is possible that this is ultimately due to the OAO 2 calibration, which formed the basis for this preliminary calibration. When applied to the spectral region below 1,200 Å where the spectral response is dropping rapidly, this early calibration is much less accurate and the data below Lyα in the following figures should be treated with caution.

Table 1 Hot stars observed by IUE			
Object	Spectral type	V (mag)	Notes
BD+75°325	sdO	9.5	
HZ43	DAwk	12.8	EUV source
NGC6826	O3f	10.5	Central star of planetary nebula
SS Cyg	G+em lines	9.1*	Dwarf nova
		11.0*	
η Car	pec	6.2	UV-IR object

* Magnitude estimated from FES counts at time of observation.

HZ43

The white dwarf HZ43 (spectral type DAwk) has long been known to be one of the hottest objects from ground-based observations^{4,5}. In recent years, it has been an object of considerable interest because it was the first extra-solar source of EUV radiation to be detected^{6,7}. The IUE spectrum of HZ43, shown in Fig. 1, shows no obvious spectral features other than Lyα. This is consistent with the interpretation that HZ43 is a white dwarf in which gravitational separation has already taken place so that hydrogen would be the only observable element in the stellar atmosphere. The Lyα feature observed here is probably essentially stellar rather than interstellar in origin, as the star is close to the Earth (about 60 pc)^{8,9} and the gravity of the star is high (log g > 7.7) (ref. 10). Although Lyα is the only prominent feature, there appears to be 'fine structure' in the spectrum near 1,720 Å, which if confirmed could be ascribed to N IV.

Fig. 2 Relative flux distribution of BD+75°325

Table 2 Low dispersion spectral images obtained by IUE

Object	Image*	Date (day 1978)	Start (GMT)	Aperture	Exposure time (s)	Comments

* Images are designated by camera and sequence number. SWR=short-wavelength redundant camera; LWP=long-wavelength prime camera, SWP=short-wavelength prime camera, LWR=long-wavelength redundant camera

The IUE flux distribution indicates a black body temperature between 50,000 and 100,000 K with negligible interstellar extinction, values that will be improved when the system is fully optimised and calibrated. Auer and Shipman¹⁰ from EUV and visual data estimate that the stellar parameters lie between the following limits: $T_{\text{eff}} = 55,000$ K, $\log g = 7.7$, $M = 0.4M_{\odot}$ and $T_{\text{eff}} = 70,000$ K, $\log g = 7.9$, $M = 0.5M_{\odot}$.

BD + 75°325

At a visual magnitude of 9.5, BD + 75°325 (spectral type sdO) is one of the brightest hot subdwarfs in the sky and has been studied in detail by Peterson¹¹. The only prominent lines in the visual spectrum are due to hydrogen, helium and nitrogen. The IUE spectrograms show a similar picture: absorption lines of He II, N IV and N V are strong, while lines of C III and C IV are below the threshold of detection. The long wavelength spectrum (not shown) indicates that the Paschen series of He II is stronger than in young O stars like ζ Pup¹², probably due both to helium enrichment and to Stark-broadening. The short-wavelength spectrum, shown in Fig. 2, indicates that nitrogen lines are strong, totally in absorption, and apparently at their rest wavelengths. The absorption in the spectral region, 1,600–1,750 Å, is real and most probably includes He II $\lambda 1640$. There is no evidence for the presence of the C IV resonance doublet at 1,550 Å. The apparent emission feature shortwards of Ly α is a noise spike.

In her study of the visual spectrum of BD + 75°325, Peterson¹¹ found that it was impossible to construct an LTE model atmosphere which predicts the observed characteristics of the star: the ionisation equilibrium between N III and N IV implies the atmospheric parameters, $T_{\text{eff}} = 55,000$ K, $\log g = 5.3$ and $N_{\text{He}}/N_{\text{tot}} = 0.6$, while the helium lines imply the parameters $T_{\text{eff}} = 45,000$ K, $\log g = 5.3$ and $N_{\text{He}}/N_{\text{tot}} = 0.6$. It is probable that much of the discrepancy is due to non-LTE effects. If so, it is

Fig. 4 Comparison of IUE spectrum of NGC6826 with Copernicus spectra of ζ Pup and o Per. The Copernicus spectra have been smoothed by a running box average whose width corresponds roughly to 6 Å.

Fig. 5 Relative flux distribution of SS Cyg near quiescence

important to obtain line strengths and profiles of important transitions of helium and nitrogen. High-dispersion spectra of BD + 75°325 could be obtained easily by IUE and should provide useful constraints on the physical properties and chemical abundances in the stellar atmosphere

NGC6826

Figure 3 shows the short wavelength spectrum of NGC6826. The spectrum of the central star of this planetary nebula clearly has a high excitation, as would be expected from its visual spectral type of O3f (ref. 13). The most prominent lines are the resonance lines of N V $\lambda 1240$ and C IV $\lambda 1550$, as well as O V $\lambda 1370$ and N IV $\lambda 1718$ which arise from excited levels. The UV spectrum is very similar to that of the young star ζ Pup¹⁴, also an early Of star, with the strong lines all having P-Cygni profiles which indicate mass-loss from the central star. The interaction of the stellar wind with the surrounding nebula would be an interesting topic to pursue.

Although the stellar contribution is dominant, the spectrum of this object is a composite of stellar, nebular and interstellar spectra. Nebular emission of C III $\lambda 1909$ is clearly visible and fills the large aperture ($10'' \times 20''$). Nebular and/or interstellar absorption is also present: the strongest such feature, at 1,305 Å, is undoubtedly a blend of O I, Si II and P II resonance lines, all of which are of too low ionisation to belong to the stellar atmosphere. Figure 4 compares the spectral region containing this feature with degraded Copernicus U2 spectra of ζ Pup, which has very little reddening ($E(B - V) = 0.03$), and o Per, a B1 III star with heavy reddening ($E(B - V) = 0.32$). Note that the $\lambda 1305$ feature does not appear in ζ Pup but does appear in the spectrum of o Per with a strength comparable with that in the spectrum of NGC6826. If the relation between hydrogen column density and reddening given by Bohlin¹⁵ is used with the colour excess derived from Kaler¹⁶, a value of $\sim 10^{20} \text{ cm}^{-2}$ is obtained which is rather low for the observed line strength. There is therefore a possibility that some of the 1,305 Å feature may be nebular in origin but because of the loose nature of the correlation between hydrogen column density and reddening,

this would need to be established by other evidence. If the presence of nebula absorption lines were confirmed, for example, by high dispersion spectra, it would provide an important new tool for abundance analysis.

SS Cygni

The properties of the dwarf nova, SS Cyg, and dwarf novae in general have been reviewed by Warner¹⁷; since when, it was discovered¹⁸ and confirmed¹⁹ that SS Cyg is a soft X-ray source. The general explanation for these properties is that dwarf novae are binary systems in which material is being transferred from a low-mass secondary, through an accretion disk, to a white-dwarf companion. The 'hot spot', where the stream of transferred matter collides with the disk, and the disk as a whole are responsible for the UV and visual radiation.

UV spectra of SS Cyg were obtained on two occasions during the commissioning phase of IUE: the first during outburst, and the second near quiescence. The two spectra, which are shown in Figs 5 and 6, show the effect of an outburst. The most outstanding change is an increase in the continuous flux at outburst causing a reversal in the appearance of the CIV $\lambda 1550$ resonance doublet: near quiescence, it is an exceedingly strong emission feature, while during outburst it is a weak absorption or P-Cygni feature.²⁰ In addition, emission at NV $\lambda 1240$, Si IV $\lambda 1400$ and He II $\lambda 1640$ are visible near quiescence, while during outburst these lines either disappear or go into absorption. The great strength of CIV emission near quiescence is important as an indicator of physical conditions in the disk.

A second change is an apparent increase in colour temperature during the outburst as expected from UV photometry of SS Cyg by Holm and Gallagher²⁰. The IUE spectra are similar to a black body temperature near 40,000 K during outburst maximum, and about 30,000 K near quiescence. As the interstellar extinction of this object is minimal ($E(B-V) \approx 0.08$) (ref. 20) these estimates should only slightly underestimate the intrinsic black-body colour temperatures of SS Cyg in this wavelength range. Of course, these values should be treated with caution because they are highly dependent on the absolute calibration, and they are not directly translatable to physical temperature until the mechanism of emission (probably optically thick free-free emission) and the range in physical conditions within the disk are specified.

η Car

One of the most remarkable objects in the sky is the star (or starlike object), η Car. Listed as a 4th mag star in Bayer's atlas of 1603, it brightened in the early 1800s until in 1843, it outshone every star in the sky except Sirius. For the past century, it has hovered between about 6th and 8th mag. The evolutionary status of this object is not understood, and theories about its nature²¹ are diverse, ranging from the hypothesis that it is a young, massive star either approaching the main sequence or somewhat evolved from it, to the hypothesis that it is a non-thermal or non-stellar object, such as a supernova remnant. Its present spectrum²²⁻²⁴ in the visual, consists of a continuum on which are superposed numerous emission lines (both permitted and forbidden) of Fe II, Cr II, Ni II, Na I, and so on, as well as the

Fig. 6 Relative flux distribution of SS Cyg during outburst.

Fig. 7 Relative flux distributions of η Car

hydrogen Balmer series. According to Rogers and Searle²⁴, the continuum contributes 70% and the emission lines 30% of the visual radiation. The object is heavily reddened both by interstellar material in the line of sight and by circumstellar gas and dust.

The IUE spectra of η Car, shown in Fig. 7, indicate that the UV spectrum is very complicated. One of the most outstanding characteristics is that the spectrum appears to change from an emission-line-dominated spectrum at longer wavelengths to an absorption-line-dominated spectrum at shorter wavelengths. According to Rogers and Searle, there are only a few spectral windows in the visual region of the spectrum which are free of emission lines, and in these regions the continuum is featureless. However, in the far-UV region from 1,150 to 1,600 Å, there appear to be about 30 absorption features visible, but it is not clear at this stage whether these are real or whether they are simply regions where there are no emission lines.

Another unusual characteristic of the UV spectrum is a flux discontinuity, near 2,400 Å. Although interstellar extinction must play a part in depressing the flux in this spectral region, the drop is too precipitous to be ascribed totally to the interstellar $\lambda 2200$ extinction bump. Possibly it is due to a chance lack of emission lines below 2,400 Å. In any case, the discontinuity greatly increases the difficulty of inferring the amount of extinction from the observed UV flux distribution.

Initial IUE observations of four cool stars are reported. Observed fluxes and surface fluxes are given for several UV emission lines in the spectral range 1,175–2,000 Å, obtained at low and high dispersion with the short-wavelength spectrograph and camera. These lines are formed in the outer atmospheres of these stars, in regions presumably analogous to the solar chromosphere and transition region. The surface fluxes in the lines increase along the sequence: quiet Sun, ϵ Eri, λ And, α Aur, and HR1099. The 2.8-d RS CVn-type binary HR1099, observed on 1 March 1978 near the end of a major flaring episode, has line surface fluxes ~ 100 times that of the quiet Sun, similar to those seen in solar flares. Line profiles and flux ratios in multiplets for Capella are presented, and comments given on the opacity of the lines and on a tendency of line width to increase with temperature of formation.

THE IUE has made it feasible to study for the first time UV spectra of many late-type stars. These emission-line spectra originate in chromospheres, coronae, and circumstellar envelopes, and they contain information about mass loss from late-type stars. Before IUE, Copernicus and rocket- and balloon-borne experiments could study only the strongest lines in a few very bright stars. Here we present observations of α Aur (Capella), λ And, HR1099, and ϵ Eri. These data were obtained during the science commissioning phase of IUE and Table 1 gives the circumstances of the observations. Although these data were obtained before reoptimisation of the telescope and detectors, they indicate the ultimate capabilities of IUE. In this first sampling of cool stars, we have chosen those expected to have bright emission-line spectra and have concentrated on the 1,175–2,000 Å region, where most of the important emission lines are located.

α Aurigae (Capella)

Capella is a double-line spectroscopic binary system, consisting of a G5 III primary (Capella A) and a G0 III secondary (Capella B)¹. It was chosen as the first IUE scientific target because it is easily identifiable and is known to have several bright UV emission lines.

Evidence for a chromosphere in at least one component consists of emission cores in the Ca II H and K lines², the Mg II h

($\lambda 2803$) and k ($\lambda 2796$) lines³, and H I Ly α ^{4,5}. Using the Ca II and Mg II line fluxes and identifying the chromospheric spectrum with Capella A^{3,4}, Kelch *et al.*² derived a model for the chromosphere and upper portion of the photosphere of this star. Material at temperatures above 20,000 K is indicated by UV emission lines of C II–IV, Si II–IV, N V, and O VI^{4–6}. Haisch and Linsky⁷ have interpreted these data in terms of a geometrically narrow conductively heated transition region similar to the transition region in a solar plage. Even hotter material is indicated by X-ray observations^{8,9} and possibly by the observed strong He I $\lambda 10830$ absorption¹⁰. The very recent HEAO-1 observations of Cash *et al.*¹¹ are consistent with a 10^7 K isothermal plasma with solar composition.

In the two exposures obtained of Capella on 9 February 1978, the large aperture ($10'' \times 20''$) included nearly all of the slightly out-of-focus stellar image. The first image was a high-dispersion exposure of the long-wavelength spectrum (1,900–3,200 Å) with the prime camera (image LWP 1022). This spectrum shows the Mg II $\lambda 2796$, 2803 lines in emission and the photospheric absorption line spectrum well exposed for 2,530–2,880 Å and 3,100–3,270 Å, but largely overexposed for 2,880–3,100 Å. The second observation was a high-dispersion exposure of the short-wavelength spectrum (1,175–2,100 Å) with the redundant camera (image SWR 1022). Qualitatively this consists of emission lines shortwards of 1,600 Å, and a photospheric absorption-line spectrum with superimposed emission lines at longer wavelengths. This spectrum is shown in Fig. 1 with the

Fig. 1 Short-wavelength high-dispersion raw spectrum of Capella (image SWR 1022) in the IUE echelle format. Important emission lines are identified.

important emission lines identified. Table 2 lists measured wavelengths of emission lines or blends and the spectrum orders. Also included are proposed identifications giving ion, multiplet number, and laboratory wavelength based on the solar line lists of Burton and Ridgeley¹² and Doschek *et al.*¹³ The relative wavelength scale was obtained from a previous Pt-Ne lamp exposure, but with 140.3 km s⁻¹ added to fit optimally the measured wavelengths of the 13 bright single narrow emission lines. This correction allows for errors in the grating dispersion constants and for the stellar radial velocity and heliocentric motions, but it prevents a velocity measurement of the emission line spectrum relative to the mean velocity of the binary system. The measured wavelengths of all bright single identified lines agree with the laboratory wavelengths to within 0.05 Å.

Relative line fluxes were determined by subtracting the background and the stellar continuum if present, and then integrating the net signal across the emission lines. These fluxes, in IUE flux units, are given in Table 2 for α Aur and for a preceding 45-s exposure of the standard star η UMa obtained with similar observing parameters. Where stellar or interstellar absorption lines are present in the η UMa spectrum, we interpolated between continuum regions on either side. Dividing the two spectra provides the best means of estimating fluxes at Earth for Capella, corrected for the echelle blaze characteristics and variable detector sensitivity with position. We have assumed the η UMa absolute fluxes of Code and Meade¹⁴, again interpolating between absorption features where necessary shortwards of 1,400 Å.

Table 1 Summary of observations

Star	Spectral type	<i>w</i> v	Binary period (d)	Phase (d)	Image no.	Dispersion	Exposure midpoint (JD 244+)	Exposure (min)	Comments

* Per Å interpolated to line centre if necessary to avoid absorption lines
† Multiplet, wavelength given is for the mean of the solar emission feature.
‡ Line not in emission in spatially-averaged solar spectrum.
‡ Uncertain.

For stars with a bright continuum like η UMa, inter-order light is not a good measurement of the background because it includes the spillover of light from adjacent orders, especially in the short-wavelength portion of the spectral format, where the orders are most closely spaced. We have therefore determined the background for η UMa as a linear function of position perpendicular to the echelle dispersion direction such that the flux in the centre of the interstellar Ly α line is zero and the background equals the inter-order signal between the two longest-wavelength orders, which are the most widely separated.

Surface fluxes (fluxes per unit area at the stellar surface) for Capella are derived from the measured fluxes at Earth and an angular diameter for Capella A of 0.0072" (ref. 2). These surface fluxes were then divided by the corresponding quiet Sun disk average values of Rottman (personal communication), which were obtained near solar minimum.

Inspection of unsmoothed line profiles is a good way of assessing the quality of the IUE observations of cool stars. The Ly α line shown in Fig. 2 is very well exposed, with signal-to-noise ratio ~ 30 near the peak. However, the interstellar hydrogen absorption feature does not reach zero intensity at line

Fig. 2 Reduced profile of the Capella Ly α line in relative IUE flux units. Location of interstellar features due to hydrogen and deuterium Ly α is noted.

centre and interstellar deuterium absorption barely appears, indicating a degraded spectral resolution due to telescope mis-focus at the time of this early observation.

Weaker lines permit measurement of line fluxes and widths, but not details of the line profiles. The C IV lines in Fig. 3 have signal-to-noise ratio ~ 8 near their peaks and an integrated line flux ratio of 2.1, compared to the solar ratio of 1.8. The O I resonance lines shown in Fig. 4 have a similar signal-to-noise ratio to the C IV lines, except for the $\lambda 1306$ line which is located near the end of order 106. Finally the C II lines shown in Fig. 5 have peak signal-to-noise of perhaps 6, yet the line fluxes and line flux ratio can be fairly accurately measured as there are about 220 pixels per line.

ϵ Eridani

This bright K2 V star was observed as a prototype late-type dwarf and also as a single star against which to compare the binary systems Capella, λ And, and HR1099. Emission in the cores of the Ca II and Mg II resonance lines had earlier provided evidence for a chromosphere in this star. From measured surface fluxes 2.3 and 1.6 times those in the average quiet Sun for Ca II and Mg II, respectively, Kelch¹⁵ derived a chromospheric model.

We obtained two low-dispersion short-wavelength observations (see Table 1), but here discuss only the well-exposed SWR 1069 image. This spectrum was calibrated using the preliminary sensitivity curves for this camera¹⁶, and is compared with the quiet Sun spectrum of Rottman (personal communication) degraded to the low-dispersion resolution in Fig. 6.

Fig. 3 Reduced profiles of the Capella C IV $\lambda\lambda 1548, 1550$ lines in absolute flux units.

Except for the relative weakness of the continuum at long wavelengths, which is expected for the cooler star, the spectrum of ϵ Eri is qualitatively similar to that of the Sun. The broad, saturated feature which covers the stellar Ly α and Si III $\lambda 1206$ lines is due to geocoronal Ly α emission filling the 10" $\times$ 20" large aperture.

Table 3 lists the emission features that clearly show up above the noise, their identification, and the fluxes at Earth. Only those features which appear in two or more stars are included. For analytical purposes, the most interesting quantities are the surface fluxes, which we determine from an angular diameter of 0.00229" derived by the V-R relation of Barnes and Evans¹⁷. The surface fluxes for ϵ Eri and for the average quiet Sun are listed in Table 3.

λ Andromedae

λ And is a single-lined spectroscopic binary with a period of 20.5 d and is a long-period RS CVn-type binary variable. This star shows bright and variable emission cores in the Ca II (ref. 18), Mg II, and Ly α lines which may be a consequence of the primary filling a significant fraction of its Roche lobe¹⁹. We obtained both high- and low-dispersion short-wavelength images of λ And. The high-dispersion image is underexposed, but it weakly exhibits emission in the following lines: Ly α ; O I $\lambda\lambda 1302, 1304, 1306$; C II $\lambda\lambda 1334, 1335$; C IV $\lambda\lambda 1548, 1550$; He II $\lambda 1640$; Si II $\lambda\lambda 1808, 1817$; and Si III $\lambda 1892$. As a result of the faintness of this exposure, we observed the star again but in low dispersion. This spectrum was calibrated in a manner similar to that of ϵ Eri and is shown in Fig. 6. Table 3 gives line fluxes and surface fluxes, for which an angular diameter of 0.00274" was assumed.

The low-dispersion spectrum was obtained at spectroscopic phase 13.751 d with respect to the orbital elements of Walker²⁰. λ And has a photometric period of 50–55 d. In unpublished UBV photometry Hall found that λ And was brightest on JD 2,443,360 and 2,443,420. Thus our observations were obtained very near photometric maximum, when IUE was observing the unspotted and presumably least active hemisphere.

HR1099

Bopp and Fekel²¹ pointed out that HR1099 is a double-lined spectroscopic binary, and is one of the shortest-period RS CVn-type binaries. They show that the Ca II H and K and H α emissions are due mainly to the primary star. HR1099 also shows Ly α , Mg II h and k, radio, and X-ray emission²²⁻²⁴. We observed this object on 1 March 1978, towards the end of the most intense flaring episode yet observed for this system²⁵. The observed spectrum of HR1099 is shown in Fig. 6 and fluxes are given in Table 3. From the G5 V spectral type²⁶, we derived $V-R=0.61$ and hence an angular diameter of $0.000644''$. Our observation occurred 2.4488 d after conjunction²⁷, when the primary, and presumably more active, component was near maximum velocity of approach²¹.

Discussion

Detailed analysis and atmospheric modelling of these data will be reported elsewhere, and both deeper exposures and observations at different phases of the binary targets would be helpful. In the meantime it is important to discuss and assess these new data qualitatively.

First, there is no clear evidence of 10^6 K or hotter material in the 1,175–2,000 Å spectral region, but as only very weak coronal lines such as [Fe XII] $\lambda\lambda$ 1242.03, 1349.38 occur in this spectral range, this conclusion is not unexpected. These lines do not appear in the quiet Sun disk spectrum but they do appear off the limb above active regions and during flares²⁸. The hottest plasma clearly identified in our data has a temperature of 2.6×10^5 K, as indicated by the O V λ 1371 line in HR1099 and λ And. However, we point out that the broad feature at 1,355 Å in HR1099 and ascribed to O I(1) λ 1355.6 and λ 1358.5 could

include a contribution due to [Fe XXI] λ 1354.1, which is bright in solar flares²⁹.

Second, there are important qualitative differences among the five spectra shown in this paper (Figs 1 and 6). In both the Sun and Capella the photospheric absorption-line spectrum is clearly present at wavelengths longwards of 1,500–1,600 Å, but is very weak in the cooler stars. It is likely that Capella B is mainly responsible for the observed photospheric spectrum of Capella.

Line ratios often vary strongly from star to star. To facilitate comparison, Table 4 lists the ratios of accurately measured line surface fluxes to corresponding values for the average quiet Sun. Average values are given for ions whose lines are formed in similar temperature ranges³⁰, and we have included Ly α , Ca II, and Mg II data from other sources.

There are several trends in these data. First, the O I resonance lines are often much brighter than the other chromospheric ($T < 10^4$ K) lines, and the He II λ 1640 line is often much brighter than the other transition-region ($T > 3 \times 10^4$ K) lines. The O I anomaly is probably due to the Ly β pumping mechanism that operates in α Boo³¹ and the Sun³², and the He II λ 1640 line can be formed by recombination following photo-ionisation of He II by $\lambda < 227$ Å coronal photons³³. Thus, when the O I and He II lines seem anomalously bright, one may infer that these fluorescent processes are more important compared to collisional excitation than in the Sun.

In ϵ Eri the chromospheric and transition-region lines, except for He II λ 1640, are all about three times as bright as in the Sun; hence, the basic structure of the outer atmosphere of this prototype K dwarf bears similarities to that in the Sun. The factor of 3 increase in brightness of the chromospheric lines has been explained by a steeper temperature gradient in the lower

chromosphere¹⁵, which results in higher densities and thus more collisional excitation of the lines. If the transition region in ϵ Eri is geometrically thin and conductively heated as in the Sun, then the strength of its lines is proportional to the transition region pressure⁷ and this pressure should be a factor of 3 larger in ϵ Eri than in the quiet Sun. λ And is similar to ϵ Eri except that there seems to be twice as much material in the transition region.

Table 4 Line surface fluxes/average quiet Sun

Ions	Temperature	ϵ Eri	λ And	α Aur	HR1099	Ref.
C I, Si I, Si II	$4-6.5 \times 10^3$	2.4	4.2	4.9	70	This work
O I $\lambda\lambda 1302, 4, 6$	$\sim 6 \times 10^3$	3.8	16	19	63	This work
Ca II, Mg II	$\sim 6 \times 10^3$	2.0	4.6	3.7	50	2, 15, 22
Lya	2×10^4	1.3*	3.9*	1.5*	50*	5, 22, 26
C II, C III	$4.5-9 \times 10^4$	3.3	4.7	20	100	This work
He II	$\sim 8 \times 10^4$	12	22	20	190	This work
C IV, Si IV, N V	$0.8-3 \times 10^5$	4.4	9.5	26	84	This work

* Uncorrected for interstellar absorption.

Capella and HR1099, by comparison, are very different from the quiet Sun. Capella shows considerably more material in its transition region than the Sun, whereas HR1099 shows large enhancements in both the transition region and the chromosphere. Since the surface fluxes for HR1099 are enhanced over the quiet Sun fluxes by a factor of 10^2 , similar to the typical enhancement of permitted lines during solar flares³⁴, a solar-like flare may have covered most of the stellar surface or a far more intense flare may have covered a small portion of the surface during this episode.

Third, for Capella the line surface fluxes for ions formed at $T > 3 \times 10^4$ K are typically 20 times larger than for the quiet Sun. By comparison, Vitz *et al.*⁵ obtained values only 10 times larger than for the quiet Sun. This apparent factor of two discrepancy is due mainly to the different angular diameters for Capella A assumed here ($0.0072''$) and by Vitz *et al.*⁵ ($0.0094''$) in converting observed flux to surface flux. Measured fluxes at Earth are in good agreement (within 15%) for the $\lambda\lambda 1206, 1240, 1305$, and 1550 features, but the IUE values are about 65% larger for the $\lambda\lambda 1335$ and 1397 features formed by the C II and the Si IV and O IV lines. We cannot say with certainty at this stage whether the discrepancy in the $\lambda\lambda 1335$ and 1397 fluxes is due to measurement error or represents real changes in the emission from Capella. We suspect, however, that the discrepancy results from the preliminary nature of our calibration scheme, as the $\lambda 1550$ fluxes, due mainly to C IV, agree and there is no evidence for large changes in emission-line fluxes with phase except for O VI.

Fourth, in the high-resolution Capella spectrum there is no systematic trend in wavelength residual with ionisation potential or presumed temperature of maximum abundance. Thus we see no evidence for the onset of a stellar wind at temperatures of $100,000-200,000$ K, as previously seen in the O VI $\lambda 1032$ line (formed at $300,000$ K) by Dupree⁴ at phase 38.2 d.

Fig. 5 Reduced profiles of the Capella C II $\lambda\lambda 1334, 1335$ lines in absolute flux units

Fig. 6 Low-dispersion short-wavelength spectra of a, HR1099, b, λ And, and c, ϵ Eri in absolute flux units are compared with the quiet Sun (d) spectrum degraded to $6 \text{ \AA}$ resolution. Important lines are identified. The stellar Ly α and Si III $\lambda 1206$ lines are covered by saturated geocoronal Ly α emission.

There is, however, a significant increase in line width (FWHM) with ionisation potential—C I ($0.28 \text{ \AA}$), O I ($0.47 \text{ \AA}$), Si II ($0.43 \text{ \AA}$), C II ($0.82 \text{ \AA}$), Si III ($0.69 \text{ \AA}$), C III ($0.54 \text{ \AA}$), Si IV ($0.67 \text{ \AA}$), C IV ($0.89 \text{ \AA}$), and N V ($0.71 \text{ \AA}$). These widths, except for C I and N V, are probably accurate to $\pm 10\%$. This trend suggests that turbulent motions increase with height in the outer atmosphere as occurs in the Sun¹⁵. The C II and C IV lines appear to be anomalously broad compared to the trend, perhaps due to significant optical depths in these lines.

In Capella, the emission lines are all single, as would be expected at phase 77.711 d (based on the orbital elements of Batten and Erceg)³⁵ when the radial velocity difference between the two stars is very small. Also, no lines seem to show a narrow component (from Capella A) superimposed on a broader component (from the more rapidly rotating Capella B)^{36,37}. Thus we cannot ascribe the observed spectrum to a specific star on the basis of our data alone, but instead rely on previous work^{3,4} for evidence that Capella A is the emitting star.

Finally, line flux ratios for O I $\lambda 1306/\lambda 1304/\lambda 1302$ and C II $\lambda 1335/\lambda 1334$ in Capella are close to unity and similar to the solar ratios, implying large optical depths in the lines. On the other hand, the C IV $\lambda 1550/\lambda 1548$ ratio is 2.1, similar to the solar ratio, 1.8, and to the ratio of *gf* values for the lines, 2.0. We conclude that these lines must be effectively thin (not thermalised), but that the anomalous width of the lines may be due to optical-depth effects. The Si II $\lambda 1817/\lambda 1808$ ratio is 3.1 in Capella, 2.8 in ϵ Eri, and 2.4 in HR1099, compared to the *gf* value ratio, 2.0. The fact that these ratios are in excess of the optically thin value is at first sight surprising, but may be explained if the lines at $1,808.4$ and $1,816.9$ become optically thick whilst the $1,817.4$ component remains optically thin. Photons may then be transferred from $1,804.4$ to $1,817.4$, thus increasing the ratio of $1,817.4$ plus $1,816.9$ to $1,808.4 \text{ \AA}$.

We thank G. J. Rottman for permission to cite his solar data, and D. S. Hall for comments on the RS CVn-stars and permission to cite unpublished photometry.

Results from a preliminary study of interstellar absorption lines in the spectra of the three stars HD149757, HD93521 and HD153919, observed by the IUE during its commissioning phase are presented. They demonstrate the capabilities of the IUE for interstellar research. Results from a preliminary study of the emission line spectrum of the planetary nebula NGC7027 are outlined and used to study its interstellar reddening.

THE IUE with its wide spectral coverage, roughly 1,150–3,200 Å embracing many of the resonance lines of the common elements, its excellent sensitivity throughout this band, and its large resolving power of 10^4 when used in the high dispersion mode, is a unique instrument for studying the interstellar medium. Atomic species that can be observed include H I, D I, Be I–II, B I–III, C I, C II, C IV, N I, N V, O I, Na I, Mg I–II, Al I–III, Si I–IV, P I–III, S I–III, Cl I, Ca I–II, Sc III, Ti I–III, V I–III, Cr I–II, Mn I–II, Fe I–II, Co I–II, Ni I–II, Cu I–II and Zn I–II. In some cases, such as C I, C II, O I, Si I, Si II, Fe II, not only the resonance lines, but also lines originating from excited fine-structure levels within the ground state are accessible. In addition to the atomic species, several diatomic and polyatomic molecules which are thought to be abundant in interstellar clouds have lines within the IUE band. Obvious candidates for such observations are OH, CO, C₂ and CH; the first, with its

transition near 3,080 Å, and the last, with its transitions near 3,137–3,146 Å, are also accessible from the ground. Some of the rarer molecular species which still might be detected in favourable circumstances include H₂O, MgH⁺, CH₃, CO⁺, NO, NO⁺, SiO and CS.

In the low dispersion mode IUE can also provide important new information about the absorption and scattering characteristics of interstellar dust.

Fig. 1 Observed spectrum of HD149757 without background and echelle ripple correction. The section of the spectrum contained in orders number 110–118 of the short-wavelength spectrograph is plotted showing strong narrow absorption lines due to interstellar C I, Si II and S II. The features indicated by R are due to fiducial marks. Vertical lines mark the ends of echelle orders.

Fig. 2 Spectrum of HD149757 contained in orders number 90-89 of the long-wavelength spectrograph, showing strong absorption lines due to interstellar Mn II and Fe II.

During the commissioning phase of IUE the spectra of three stars, HD93521, HD149757 and HD153919, were obtained in order to study their interstellar absorption lines. As a fourth target the planetary nebula NGC7027 was observed in order to study its emission line spectrum. Table 1 lists these targets and the observations obtained.

The star HD149757 (ζ Oph) has been selected as a prime target for the study of interstellar absorption lines for many reasons. It is a bright source, it has been exceedingly well studied in the UV, in particular by the Copernicus satellite¹, thus providing an excellent basis to demonstrate the IUE capabilities in comparison with these other instruments. It also has a large H_2 column density, suggesting that other molecules might be found along this line of sight. As the Copernicus observations did not cover all UV wavelengths equally well, the IUE observations will extend the earlier data.

HD93521 was observed as a photometric standard as well as for the study of interstellar absorption lines. It is one of the few

Fig. 3 The spectrum of HD149757 in the neighbourhood of the C I λ 1656.928 line, corrected for the inter-order background. Note the strength of the absorption lines originating from excited levels within the ground state of C I (* and ** indicate 1st and 2nd excited levels). The wavelength scale plotted is the one assigned during the data reduction process. The laboratory wavelengths indicated on the figure have been shifted by a constant amount of -0.25 Å to correct for an offset in this scale.

early type stars known to be at a large distance from the galactic plane at $z = 1,570 \text{ pc}$. Also, its interstellar line spectrum shows a multiple component structure with a velocity separation of several tens of km s^{-1} (ref. 2), which is resolvable by the IUE.

HD153919 was primarily observed as it is the optical counterpart of an X-ray source (3U1700-37); and is discussed by Dupree *et al.*³ in the following article. However, it is one of the most highly reddened stars observed by IUE during the commissioning phase making it an excellent candidate for a search for interstellar absorption lines from rare species.

Absorption lines in the spectra

We now present illustrative results from a study of interstellar absorption lines in the spectra of the three stars HD149757, HD93521 and HD153919. The analysis is preliminary and based on data that had not been fully processed at the time.

HD149757

Figures 1 and 2 show two 30 Å bands at $1,250\text{--}1,280 \text{ Å}$ and $2,575\text{--}2,605 \text{ Å}$ extracted from the short-wavelength and long-wavelength spectrograms. The first of these covers the echelle orders 110-108 in the short-wavelength spectrograph and the data are uncorrected for the echelle ripple. The second covers the orders 90-89 in the long-wavelength spectrograph. In both cases, the strong interstellar lines from S II, Si II, Mn II and Fe II are clearly visible and have an equivalent width of the order of 100 mÅ . In Fig. 3 is plotted a 3 Å segment of the short-wavelength spectrograph around $1,657 \text{ Å}$ where several C I lines occur from either the ground level proper or from excited levels within the ground state term. The equivalent width of the C I λ 1656.928 line is $\sim 70 \text{ mÅ}$. Note that the wavelength scale plotted is the one assigned during the data reduction process. It has an offset of $\Delta\lambda = 0.25 \text{ Å}$ which has been taken into account when locating the expected line positions.

In Fig. 4 the data for five spectral lines observed by the Copernicus satellite are compared with those observed by the IUE. These lines and their equivalent widths as measured by Morton¹ are S III λ 1190.206 (67 mÅ), Si II λ 1190.418 (132 mÅ), P II λ 1301.87 (15.6 mÅ), O I λ 1302.169 (201 mÅ) and Mg II λ 2802.704 (290 mÅ). The Copernicus profiles have been obtained by averaging two, three and two scans, respectively, whereas the IUE data are from a single image. Figure 4 demonstrates that the resolution of the IUE as compared to the Princeton spectrophotometer is somewhat degraded but that features separated by 0.2 Å can still be clearly resolved. Also note the much lower noise in the Mg II λ 2802 line, as observed by the IUE.

Fig. 4 Comparison of spectral line profiles as observed by the Copernicus satellite (Morton 1974) and by IUE in the spectrum of HD149757. The IUE wavelength scale has not been corrected for an offset.

Table 2 shows a comparison of the equivalent widths measured by the two systems. A statistical assessment shows that the IUE values are on average 10% higher than Copernicus and the r.m.s. deviation of the ratio of the two is $\pm 16\%$. This agreement is very satisfactory, particularly as the IUE data reduction and calibration were in their early stages and most of the large differences do occur for lines which are at present difficult to measure on IUE spectra.

HD93521

To study interstellar matter well above the galactic plane, the halo star HD93521 has been observed. It is located at $b^{\text{II}} = 62^\circ$ at a distance of 1,778 pc, giving $z = 1,570$ pc. The absorption lines originating from the local gas and the high z gas have a large velocity separation. The strongest components occur at v (heliocentric) = -12 km s^{-1} and -56 km s^{-1} with additional components at $+5 \text{ km s}^{-1}$ and -34 km s^{-1} (see ref. 2). For the strongest two components the HI column density is $2 \times 10^{19} \text{ cm}^{-2}$ and $8 \times 10^{19} \text{ cm}^{-2}$ (ref. 4). H_2 has been detected in the -12 km s^{-1} component⁵.

Figures 5 and 6 show the absorption line profiles as observed by IUE. For comparison the Ca II K-line profile measured by Münch and Zirin² is included in Fig. 5. In plotting the IUE results we have kept the wavelength scale as assigned during the data reduction process but shifted the marks that indicate the expected line position by -56 km s^{-1} and -12 km s^{-1} with respect to this scale. The main components are clearly seen in the C I $\lambda 1277.245$, C II $\lambda 1334.532$, C II $\lambda 1335.708$ and Si II $\lambda 1259.520$ lines. In these cases the -56 km s^{-1} component seems to be weaker than the -12 km s^{-1} one, consistent with the optical and HI results. In the case of the Si II $\lambda 1190.418$ and S III $\lambda 1190.206$ lines the same may hold but a deconvolution of

Fig. 6 As Fig. 5, except that interstellar absorption lines originating from highly ionised species have been plotted

the observed profiles would be required to demonstrate this. An enhanced strength of the -56 km s^{-1} component which is associated with the gas at $z \approx 500$ pc (refs 2, 4 and 6) is apparent in the Al III $\lambda 1854.720$ line. The same may be true for the C IV $\lambda 1550.774$ and Si IV $\lambda\lambda 1393.755, 1402.769$ lines. However, the N V $\lambda\lambda 1238.821, 1242.804$ lines do not seem to follow this trend. Indeed there is no strong evidence for the presence of interstellar N V.

HD153919

HD153919 was observed primarily as an X-ray source and a more extensive discussion of its interstellar characteristics is given by Dupree *et al.*³. It shows the richest interstellar absorption line spectrum of the three stars observed. Not only are the lines considerably stronger than those in the spectrum of HD149757, which is expected from the higher reddening, but the lines also indicate a wider range of ionisation along this line of sight. Most noticeable is the strength of the lines arising from such highly ionised species as C IV and Si IV.

Figures 7 and 8 show two $30 \text{ \AA}$ sections of the spectrum of HD153919. Strong narrow absorption lines from singly ionised species like Si II, P II, Mn II and Fe II are clearly visible as well as the C IV lines at $1,550 \text{ \AA}$. As indicated in Fig. 7, lines arising from excited levels within the ground state are strong in this spectrum. This is even more evident from Fig. 9, where we have plotted the spectrum in the neighbourhood of the C I $\lambda 1656.928$ line. Figure 10 shows the evidence for the more highly ionised

Fig. 7 Observed spectrum of HD153919 with neither background nor echelle ripple correction. The section plotted is contained in the echelle orders number 90-89 in the short-wavelength spectrograph and shows evidence for strong interstellar absorption lines due to single as well as multiple ionised species

species such as Si III, Al III, C IV and Si IV. The presence of N V remains doubtful. X-ray ionisation of the interstellar medium local to this source might explain the presence of these high ion stages^{3,7}.

Emission lines in the spectrum of NGC7027

NGC7027 has been selected as a prime target for the study of its emission lines in the UV on several grounds. First, it was known to exhibit a strong UV line spectrum from the work of Bohlin *et al.*⁸. These data have been obtained with a rocket-borne 33 cm telescope feeding a spectrograph that yielded 46 Å mm⁻¹ dispersion in the 1,300-2,900 Å region. Second, with its angular size of 10 arc s, the nebular image fits nicely in the 10×20 arc s entrance slot of the IUE spectrograph. Third, and perhaps most

Fig. 8 As Fig. 7, except that a 30 Å section from the long-wavelength spectrograph of HD153919 has been plotted, showing the great strength of the Mn II and Fe II lines (see Fig. 2).

important, NGC7027 is now the one planetary nebula for which the emission spectrum has been studied all the way from the radio band⁹, through the near IR (10-12.5 μm (ref. 10); 4-8 μm (ref. 11); 2-4 μm (ref. 12); 0.8-2.7 μm (ref. 13)), the optical (Kaler *et al.*¹⁴ discuss the entire band from 3,050 to 8,600 Å), into the UV. These extensive data should provide an excellent basis for the detailed comparison with model calculations for this planetary nebula.

NGC7027 was observed three times with IUE. Low resolution spectra of the long-wavelength and the short-wavelength range and a high resolution spectrum of the long-wavelength range were obtained. Figure 11 shows the low resolution spectra. The intensities have not been corrected for the IUE sensitivity response but the zero point of the wavelength scale was corrected on the basis of identified lines.

The most notable feature in the spectrum is the great strength of the emission lines, most of which are readily identified. These are listed in Table 3, together with preliminary flux values. The fluxes were determined from sensitivity curves derived from observations of standard stars as described by Boggess *et al.*²³ but with the TD-1 (S2/68) fluxes as standard²⁴. The relative line intensities within each spectrum should be accurate to better than ±30% for the stronger features, and roughly ±50% for the weaker ones, except for λ > 3,100 Å where the sensitivity is low and the ±50% error applies to all lines. To combine the data from the two spectral ranges, the long-wavelength data were fitted to the short-wavelength data by using the intensity of the

Fig. 9 The spectrum of HD153919 in the neighbourhood of the C I λ1656.928 line. Note the great strength of the absorption lines originating from excited fine structure levels within the ground state of C I. The wavelength scale is the one assigned during the data reduction process

C III λ1909 line which is seen in both spectra. A comparison of these results with those from other experiments shows excellent agreement with the intensities as observed by the ANS satellite¹⁵ for the C IV λ1550 line, and consistent agreement with the results from the rocket experiment of Bohlin *et al.*⁸, which are, however, systematically smaller, by a factor of ~2. For λ >

Table 2 Equivalent widths for strong lines in the spectrum of HD149757 as measured by Copernicus (COP) and IUE

Ion	λ _{Lab} (Å)	W _λ (COP) (mÅ)	W _λ (IUE) (mÅ)	Ion	λ _{Lab} (Å)	W _λ (COP) (mÅ)	W _λ (IUE) (mÅ)
C II	1,334.532	189	224	Si II	1,193.289	147	75†
C II*	1,335.703	140	184†	Si II	1,190.416	132	130
N I	1,200.711	133	194†	S II	1,259.520	112	148†

O I	1,302.169	201	198	Mn II	2,605.697	111	115
Mg I	2,852.127	218	196	Mn II	2,593.731	116	163
Mg II	2,802.704	290	337†	Mn II	2,576.107	138	137
Mg II	2,795.528	312	309	Fe II	2,599.395	226	247
Si II	1,526.708	190	156	Fe II	2,585.876	214	174
Si II	1,304.372	132	127	Fe II	2,382.034	238	259
Si II	1,260.421	170	223‡	Fe II	2,373.733	120	185†

As strong lines we have arbitrarily defined lines that have an equivalent width of more than 100 mÅ as measured by Morton in the Copernicus spectrum of HD149757. Uncertainties (denoted by †) arise in the IUE data if the line is close to the end of an order or in a badly exposed part of the image. The Si II λ 1,260.421 line is blended by the Fe II λ 1,260.542 line (denoted by ‡).

Fig. 10 Sections from the short-wavelength spectrogram of HD153919 showing evidence for interstellar absorption lines originating from highly ionised species. The raw wavelength scale is plotted.

3,100 Å, where the calibration is still rather uncertain, the ANS results and the measurements of Kaler *et al.*¹⁴ suggest that the IUE fluxes are systematically too low by 25–45%.

Figure 12a plots, on an enlarged scale, the 2,760–2,820 Å section of the low resolution spectrum showing a broad extended hump which contains the Mg II λ 2795, 2803 doublet. Figure 12b shows the same portion of the spectrum as observed by the high resolution mode. The wavelength scale is, in both cases, the uncorrected scale assigned during the reduction process. The two doublet lines as well as the [Mg V] line at λ 2783 Å are clearly seen. This example shows the potential of the high resolution mode of IUE for studying the emission from planetary nebulae in great detail.

While the low resolution short-wavelength spectrum of NGC7027 resembles in many ways the spectrum of NGC7662 as observed by Bohlin *et al.*¹⁶ in that C IV λ 1550, He II λ 1640 and C III λ 1909 are the most prominent features, the low resolution long-wavelength spectrum looks by comparison much richer in emission lines. Bohlin *et al.* quote the

Table 4 UV continuum fluxes in NGC7027

(Å)	Observed flux (10^{-15} erg cm $^{-2}$ s $^{-1}$ Å $^{-1}$)	(Å)	Observed flux (10^{-15} erg cm $^{-2}$ s $^{-1}$ Å $^{-1}$)
1,400	13	2,400	4
1,600	15	2,600	10
1,800	12	2,800	20
2,000	14	3,000	36
2,200	6	3,200	46

wavelengths of the components of the [Ne IV] $^2D_{3/2} \rightarrow ^4S, ^2D_{5/2} \rightarrow ^4S$ doublet to be 2,439 and 2,441 Å. However, Edlén (ref. 17 and personal communication) gives these wavelengths as 2,422.60 and 2,425.24 Å, from isoelectronic sequence extrapolations. The high resolution spectrum shows the doublet to be clearly resolved, and the wavelengths to be in agreement with Edlén's prediction, to within the accuracy of the present measurements (~ 0.5 Å). The intensity ratio $R = I(\lambda 2425)/I(\lambda 2423)$ is sensitive to electron density, being similar to the well known [O II] ratio $I(\lambda 3729)/I(\lambda 3726)$. In the limit of low densities, $R = 1.5$, and in the limit of high densities, $R = 0.16$ (the latter value being obtained using the transition probabilities of Garstang¹⁸). For NGC7027 we estimate R to be about unity (see Fig. 13) which gives a value of electron density of about 5×10^4 cm $^{-3}$.

Table 4 lists preliminary estimates of the UV continuum fluxes from NGC7027. Although the modification of the intensity distribution by extinction is substantial, the data resemble the Edistribution expected from hydrogen recombination and two-photon emission.

The UV emission lines of NGC7027 can also be used in a study of interstellar absorption. This is usually investigated by comparing reddened and unreddened stars which are believed to be intrinsically identical from their line spectra. Planetary nebulae provide a totally different method in that the recombination lines in H I and He II can be linked directly to the free-free radio emission. Because the interstellar medium is optically thin to the latter, its measured flux gives the intrinsic

Fig. 11 The low resolution *a*, short- and *b*, long-wavelength spectra of NGC7027 as observed by IUE. The flux values have not been corrected for the instrumental sensitivity. For an identification of the emission lines and corrected flux values see Tables 3 and 4.

fluxes in the H I and He II lines. A comparison with the observed line fluxes then gives directly the interstellar extinction.

NGC7027 is particularly appropriate to such a study because it is heavily reddened and has been observed extensively. Previous studies by Miller and Matthews¹⁹ used radio data and the H α , H β and H γ lines, and by Schwartz and Peimbert²⁰ who included lines at $\lambda = 1 \mu\text{m}$. With the observation of the UV He II lines with IUE an investigation of interstellar extinction over a very wide wavelength range is now possible and a brief analysis is given here. A more extensive and detailed discussion will be given elsewhere²¹.

The values of the interstellar extinction in NGC7027— $A_\lambda(7027)$ —have been derived from the IUE observations of He II lines on the basis of the method outlined above and combined with those obtained from ground-based data. The results are plotted in Fig. 14 against the values of A_λ/E_{B-V} derived by Nandy *et al.*²² from a study of early-type stars with the sky survey telescope (S2/68) on the TD-1 satellite. The excellent straight line fit of the data shows that over a wide range of wavelengths, from H α 6,563 Å to He II 1,640 Å, the reddening of NGC7027 follows closely the standard reddening law as derived by Nandy *et al.*²².

Fig. 12 Comparison of *a*, low resolution and *b*, high resolution spectra of NGC7027 in the neighbourhood of the Mg II $\lambda 2800$ doublet. The high resolution spectrum is extracted from the echelle orders number 84–82. The wavelength scale is the one assigned during the data reduction process.

For the longer wavelengths there is some discrepancy between the extinction deduced for NGC7027 and the standard extinction. The straight line of Fig. 14 does not pass through the origin and can be represented by

$$A_\lambda(7027) = \alpha \left(\frac{A_\lambda}{E_{B-V}} \right) + \beta$$

where $\alpha = 0.935$ and $\beta = 0.17$. The difference is small but there is no doubt that it is real.

An explanation of this discrepancy can be made by considering the large variation of extinction across the face of the nebula which is known to exist from the quite different distributions in the radio and optical images. Let us consider a simple two-component model in which there is a heavy local extinction over a fraction B of the total area of the source. We take the

Fig. 13 As Fig. 12, except that the spectrum in the neighbourhood of the [Ne IV] doublet has been plotted.

extinction from area B to be $\gamma(A_\lambda/E_{B-V})$ and from the remaining $(1-B)$ to be $\alpha(A_\lambda/E_{B-V})$ with $\alpha = 0.94$ as derived above and $\gamma \gg \alpha$. We can then write

$$10^{-0.4 A_\lambda(7027)} = B 10^{-0.4 \gamma (A_\lambda/E_{B-V})} + (1-B) 10^{-0.4 \alpha (A_\lambda/E_{B-V})}$$

Assuming the first term to be negligible over the wavelength range 6,563–1,640 Å where the straight line fit is good, then the two-model equation is consistent with that fit if $(1-B) = 10^{-0.4 \beta}$, giving $B = 0.145$. The value of γ can now be deduced by fitting in the red and IR regions. Using the data plotted in Fig. 14 together with the most extreme IR measurement yet available (Brackett γ at 2.166 μm , Merrill *et al.*¹²), a good fit is obtained with $\gamma = 2.0$. Hence, this simple, two component model gives

Fig. 14 Interstellar extinction measured for NGC7027 in the radio, IR, optical and UV ranges. A_λ for NGC7027 has been plotted against (A_λ/E_{B-V}) as determined by Nandy *et al.*²² from observations of about 100 reddened early type stars with the Sky Survey Telescope (S2/68) in the ESRO TD 1 satellite.

excellent agreement with the observations over the full wavelength range from the IR to the UV.

The reddening derived for NGC7027 over the range 6,563–1,640 Å is in excellent agreement with that derived from early type stars by Nandy *et al.* Most of the reddening is probably due to interstellar grains along the line of sight. The results for larger wavelengths can be explained by a local extinction, variable over the nebula, caused by grains with the same optical properties.

The first UV spectroscopic measurements of binary X-ray sources with IUE show highly variable emission from a photoionised plasma in the object HZ Her, and give evidence for localised circumsystem material in the binary source Cygnus X-1. In addition, a substantial stellar wind is found in one of the brightest identified X-ray sources HD153919. This system may be surrounded by an extensive H II region unusual in its content of high excitation ion species.

BINARY X-ray sources containing a compact object represent a class of stars that generally have been inaccessible to UV spectroscopic observations due to their faintness. Studies of these objects can potentially discern the physical conditions and dynamics of the material in the sources themselves as well as probe the interaction between the source and the surrounding interstellar medium. The IUE was used during the high priority phase of the commissioning period to obtain spectra of three stars—HD153919, HDE226868, HZ Her—that correspond to the X-ray sources 4U1700–37, Cyg X-1, and Her X-1 respectively. We report here some general characteristics of the spectra, comments on the presence of phase effects, and note the

strength of interstellar lines towards one source, HD153919, where high resolution spectra are available

Observations

A discussion of the instrument and its performance is contained in preceding articles^{1,2}. The spectra discussed here were taken over a 7-week period beginning 12 February 1978 (see Table 1). All exposures were made with the large aperture. Corrections for the effects of the radiation background and scattered light were applied by subtracting a smoothed value of the inter-order fluxes from the spectrum in each order. The adequacy of this correction for the high dispersion spectra is verified by the appearance of strong interstellar lines (that is, H Ly α at λ 1216 and C II at λ 1335) and absorption components of P Cygni profiles with flat cores of approximately zero net flux. The high dispersion spectra of HD153919 have not been corrected for the grating blaze (echelle ripple); the low dispersion spectra have been calibrated by using the preliminary determination of the instrumental sensitivity with wavelength³.

HD153919 = 4U1700–37

This binary system identified with the X-ray source⁷ is composed of a primary star classified from the optical spectrum as O6f, and a compact object—the X-ray source—orbiting essentially within

the expanding atmosphere of the primary star⁸. This source was observed at high dispersion at two phases ~ 0.35 and 0.97 , in its 3.4-d binary period.

The spectrum of the primary star shows the characteristic rich array of P Cygni profiles that has been found in other Of stars (see refs 9, 10). The lines of the strong resonance doublets of C IV ($\lambda 1550$) and Si IV ($\lambda 1400$) are shown in Figs 1 and 2 where the broad extent of these lines is apparent. Transitions that show P Cygni features and some characteristics of their profiles at phase 0.97 are given in Table 2. Here the velocity scale has been reduced to the centre-of-mass velocity of the system (-60 km s^{-1}) by using interstellar lines of low excitation and assigning them the measured heliocentric velocity of the Ca II interstellar lines¹¹, namely -14.7 km s^{-1} . The positions of line maxima were measured from tracings on a scale of $4 \text{ \AA}$ per inch; measurements to $\pm 0.1 \text{ \AA}$ can be achieved. A greater uncertainty arises in selecting the appropriate positions on the profiles since effects of the grating blaze have not been removed from these scans. This can cause a shift in the apparent maximum of a P Cygni profile and errors in the assignment of the shortwards edge. An uncertainty of $\pm 100 \text{ km s}^{-1}$ is probably a reasonable estimate of the errors in this procedure. The observed terminal velocities $\sim 2,600 \text{ km s}^{-1}$ are comparable to those found in ζ Pup (ref. 12) (spectral type O4 If) and are larger than velocities occurring in other O supergiants of later spectral type¹⁰, for example, 29 C Ma (O7 Ia:f), 9 Sge (O7.5 Ia:f), and HD151804 (O8 Ia:f).

The escape velocity from HD153919 is $\sim 720 \text{ km s}^{-1}$ assuming $M = 27 M_{\odot}$ and $R = 20 R_{\odot}$. This value is less than the maximum expansion velocities found in the P Cygni profiles indicating the presence of mass loss similar to that found in other luminous stars¹⁰.

A search was made for variations in the line profiles with binary phase. It can be argued that the structure of the wind changes when the X-ray source is present, either through ionisation of the dominant ion species that drive the wind, or by ionisation of a cavity in the expanding atmosphere of the primary star that would preferentially be in the radial direction.

The two high dispersion short wavelength spectra were taken at phase 0.32 and phase 0.97, the latter when the compact object is eclipsed. Superimposition of the broad profiles of the resonance lines Si IV, N V, and C IV shows effectively the same shape at the two phases in contradiction to some predictions¹³.

The effect of the X-ray source, if any, on the atmosphere of the primary must be confined to a region which is small compared with the extended line-forming region of the resonance transitions. Transitions from excited levels that are formed over a narrow range in velocity may be more responsive to the effects of the X-ray source. An optimum time to obtain spectra may be at phase 0.5 when the compact object is directly in front of the primary star.

The interstellar spectrum is also discussed in the preceding article by Grewing *et al.*¹⁵. It is rich as might be expected from a

Fig. 1 The region $\lambda\lambda 1523-1567$ of HD153919 (4U1700-37) taken in the high dispersion mode at two orbital phases: *a*, phase 0.32 (SWR 1027); *b*, phase 0.97 (SWR 1054). The broad stellar P Cygni profile of the C IV doublet near $\lambda 1550$ has the same appearance and extent at both phases. The strong narrow features marked at $\lambda 1548$ and $\lambda 1550$ are attributed to interstellar C IV. Other interstellar lines arising from neutral and singly ionised species are apparent; the absorption feature at $\lambda 1526.7$ is most probably interstellar Si II. There was a change of system focus between the two images; the resolution of the lower (phase 0.97) spectrum is superior to the other, as can be noted by inspection of the interstellar profiles. A correction has not been implied for the echelle blaze; the wavelength scale is given directly as inferred from the calibration lamp. The wavelength regions where the orders overlap can be noted by the double tracings; the sharp emission features near $\lambda 1539$ are of instrumental origin.

reddened source with $E(B - V) = 0.52$ (ref. 14) at a distance of 1.2 kpc (ref. 8). Many atomic species C I, Si I, Cl I are present, reflecting a large amount of cold neutral material along the line of sight. The relative weakness of C I lines originating from excited fine-structure levels suggests that the temperature is less than 50 K (J. B. Black, personal communication).

The most notable interstellar features are the strong absorption lines of the highly ionised species of Si IV and C IV (see Figs 1 and 2). The equivalent widths for the C IV doublet at $\lambda 1550.6$ and $\lambda 1548.0$, and the Si IV transition $\lambda 1402.37$ are given in Table 3. Only one of the Si IV doublet transitions is found due to the presence of a strong stellar P Cygni profile that completely absorbs the background stellar continuum. The region near

Table 1 Summary of observations

‡ Ephemeris from ref. 6.

Fig. 2 The region $\lambda\lambda 1377\text{--}1425$ of HD153919 containing the resonance doublet of Si IV at $\lambda 1394$ and $\lambda 1403$. These images were obtained at two orbital phases of the system: *a*, phase 0.32 (SWR 1027); *b*, phase 0.97 (SWR 1054). The focus of the instrument was superior when the lower spectrum was obtained; the emission peak near $\lambda 1405$ is saturated in the lower spectrum. The stellar P Cygni profiles indicate outflow velocities of $\sim 2,500\text{ km s}^{-1}$; there are no substantial differences in the profiles between the two spectra. Interstellar absorption due to Si IV is marked near $\lambda 1403$. See the legend to Fig. 1 for additional notes.

$\lambda 1240$ where interstellar N V occurs was not well exposed in our images, and upper limits to the equivalent widths are estimated from measurements of the peak-to-peak noise over widths of $0.4\text{ \AA}$ at the expected position of the lines.

The lines are assumed to lie on the linear part of the curve of growth. For Si IV, in which one line is found, this assumption gives a lower limit to the column density. The C IV transitions have central intensities which are about half of the continuum intensity; moreover their equivalent widths are in the expected 2:1 ratio confirming the assumption of unsaturated lines. The derived column densities (see Table 3) are substantially higher than those found for ζ Oph, a cooler less luminous star of spectral type O9.5 V. Highly ionised species are about twice as abundant towards HD153919 than towards ζ Pup, an O4 If star of comparable spectral type. HD153919 is at a distance of 1.2 kpc which is about 2.5 times the distance of 450 pc to ζ Pup so that we cannot rule out a large scale distribution of C IV and Si IV. However, if these ion species are confined to an H II region near the star, their higher column density may reflect the

Table 2 Velocities (km s^{-1}) of P Cygni profiles in HD153919 (Phase 0.97)

Ion	λ_{lab} ($\text{\AA}$)	Emission maximum	Absorption centre	Short edge

effects of ionisation by the X-ray source, although the observed column densities are still considerably less than those predicted by McCray *et al.*¹⁶ for HD153919.

Relative abundances of ion species may be used to discriminate between various sources of ionisation. In Table 4, we list the abundances of N V and C IV relative to Si IV that are observed towards HD153919 and towards ζ Oph and ζ Pup. These values are compared to calculations for a model of HD153919 immersed in the photoionised interstellar gas¹⁶, and for an interstellar bubble that can be caused by a strong stellar wind¹⁸. In the former case, a relatively cool but highly ionised gas can result from the EUV and X-ray radiation from HD153919. The bubble produces a conduction-dominated interface between the hot shocked (10^6 K) gas and the cold interstellar medium. This interface is the source of the absorption lines. The relative abundances that are observed (Table 4) are substantially less than those estimated for an interstellar bubble. The observations seem to support the presence of a photoionised gas near both the X-ray source and the two hot stars.

HZ Her (Her X-1)

The eclipsing binary system HZ Her contains a primary star that varies between spectral types A and F, and one of the first pulsating X-ray sources to be identified¹⁹. Periodic flux varia-

Fig. 3 The short wavelength spectrum of HZ Her at low dispersion ($\sim 6\text{ \AA}$): *a*, phase 0.76; *b*, phase 0.82. Several emission lines are apparent at both phases: N V; Si IV; C IV; and He II. The feature marked R results from a fiducial mark (reseau) on the faceplate of the camera tube.

Fig. 4 The short wavelength spectrum of HDE226868 (Cyg X-1) at two phases: a, phase 0.48, b, phase 0.93. Several strong absorption lines are noted. The feature marked R near $\lambda 1800$ results from a rescan mark.

tions are present at optical and X-ray wavelengths resulting from the binary motion of the system (1.7-d period), the rotation of the compact object and perhaps X-ray shadowing of the accretion disk²⁰ (35-d X-ray on/off period, and associated optical variability). X-ray heating of the primary star, mass accretion by the compact object, and variable absorption^{21,22} cause additional fluctuations in measured emissions.

The spectrum of HZ Her from $\lambda\lambda 1200$ –2000 was obtained at three phases during the X-ray on period of its 35-d cycle (see Table 1). Emission lines attributed to N V, Si IV, C IV and He II are clearly apparent in exposures taken at orbital phase 0.82 and 0.76 (see Fig. 3). However, a 4-h exposure centred at phase 0.98 (eclipse of the compact object) showed no line emission except for the geocoronal Ly α , suggesting that the source of UV emission is restricted in size and is located in the region on or about the opposing side of the primary, facing the compact object. An upper limit for the line and continuous flux between $\lambda 1200$ –2000 at phase 0.98 is estimated to be 1×10^{-14} erg cm $^{-2}$ s $^{-1}$ Å $^{-1}$.

The N V emission is surprisingly strong relative to C IV. Calculations²³ have been made of the line emission from a spherical, gas cloud of uniform density that is photoionised by a central X-ray source. The calculations suggest that generally C IV should be about six times stronger than N V, while our observations suggest nearly equal emission fluxes.

There is an Fe XII line at $\lambda 1242$ which could be blended with the N V doublet at $\lambda 1240$. If so, another Fe XII line at $\lambda 1350$ should be present although weaker than $\lambda 1242$, by a factor of ~ 3 in the high density limit. A feature at $\lambda 1350$ is apparent in both spectra of HZ Her (Fig. 3); if this line is indeed Fe XII, then the contribution of Fe XII at $\lambda 1242$ to the N V blend could be significant in reducing the inferred intensity of N V.

The continuum has an approximate spectral index $F_\nu \propto \nu^{-1.3}$, and is presumably due to the heating of the primary atmosphere by X rays. This is apparently in general agreement with the calculations of Milgrom and Salpeter²⁵, although their results are presented in wide bandpasses, making direct comparison difficult. The continuum flux at $\sim 1,500$ Å is $\sim 20\%$ higher at phase 0.76 than at phase 0.82; this is a marginal result, due to the

Table 4 Relative abundances of highly ionised interstellar species

Source	N(C IV)/N(Si IV)	N(N V)/N(Si IV)
HD153919 (observed)	<2.3	<2.5
ζ Oph	<0.92	<0.38
ζ Pup	1.5–2.3	<0.08
Photoionised volume ¹⁶	1.2	0.3
Interstellar bubble ¹⁸	15.9	6.3

inherent errors and the fact that for operational reasons two different cameras were used. Milgrom and Salpeter²⁵ predict a factor of two change in the continuum between these phases, which may be ruled out.

HDE226868 (Cyg X-1)

The binary system HDE226868 is identified with the X-ray source Cyg X-1. The primary star is classified²⁶ as O9.7Iab, and the X-ray producing secondary is perhaps the strongest candidate for a black hole of any compact X-ray source.

The low dispersion spectrum of HDE226868 is shown in Fig. 4 at two phases. The spectrum from the supergiant has been detected and is generally typical of a highly reddened star. This star shows broad absorption features most probably of C IV ($\lambda 1550$), He II ($\lambda 1640$), and N IV ($\lambda 1718$). The absorption, particularly of C IV, seems to be asymmetric and indicative of mass loss. Strong P Cygni emission components as found in stars of similar type from Copernicus¹⁰ are absent. There is apparently a substantial phase effect in this spectrum with the strengthening of the Si IV and C IV transitions near superior conjunction when the supergiant lies between the Earth and the compact object. These features may be similar to the absorption dips reported in soft and hard X-ray observations that occur preferentially near superior conjunction, and reflect the presence of matter between the binary components^{28–30}. Other lines such as the feature near $\lambda 1710$ may appear at phase 0.93. We should point out that the second spectrum was taken with a different camera and a better focus, so that the depth of the features could be affected.

The strength of Si IV in early-type stars seems to be a strong function of luminosity class. The equivalent width of the Si IV doublet at phase 0.93 is 6 Å, which is less than the O9.5 Ia star α Cam, but clearly more than the O9.5 V star δ Ori A (ref. 31). Thus the strength is compatible with a high luminosity for the primary.

We thank J. H. Black for contributions to the interstellar line analysis and P. Boynton and R. McCray for useful discussions.

During the commissioning phase of IUE several extragalactic objects were observed spectrally at low dispersion in the UV range $\lambda\lambda 1150\text{--}3200$: the Seyfert galaxies NGC4151 and NGC1068, the QSO 3C273, the BL Lacertae object B2 1101+38, the giant elliptical galaxy M87 and the spiral galaxy M81. The results obtained are presented and a preliminary analysis given for all six objects, discussing the continuous spectrum, extinction, emission line spectrum and absorption line spectrum, where possible for each case. Several new or confirmatory astrophysical results are obtained.

DURING the commissioning high priority target phase of IUE several classes of extragalactic object were observed at low dispersion with both the short- and long-wavelength cameras. Although the instrument was not fully optimised, scientifically useful spectra were obtained for the Seyfert galaxies NGC4151 and NGC1068, the QSO 3C273, the BL Lacertae object B2 1101+38, the giant elliptical galaxy M87 and the spiral galaxy M81. A journal of observations is given in Table 1, which includes some related optical photometry (performed by A.S.). Figure 1 gives photographic reproductions of the short wavelength spectra of four of the objects observed. All six objects are discussed separately in following sections, and are preceded by a description of the adopted calibration, which differs in detail from that used for most of the other high priority targets discussed in the accompanying articles.

Absolute calibration

The initial absolute calibration of the scientific instrument is discussed by Boggess *et al.*¹ This is based on the OAOII scale² which differs from all other recent calibrations in the region between 1,350 and 1,700 Å, having a maximum departure of about 30% at $\lambda 1550$ (refs 3, 4). Extragalactic data reduced with the absolute calibration based on the OAOII scale show a hump

in the continuum around $\lambda 1550$. The same hump has been noted in the flux distribution of hot stars observed by IUE when reduced to the OAOII flux scale^{5,1}.

We have carried out further work on the absolute calibration because this is critical for establishing the slopes of the non-thermal continua. First, we linked the calibration mainly to the TD-1 (S2/68) fluxes, supplemented by ANS data. Second, we used additional objects to HD60753, the one used by Boggess *et al.*¹ This was accomplished without additional observations as some of the high priority objects, observed during the same period as the extragalactic objects presented here, are excellent calibration standards themselves. We used the following as additional calibration objects: BD+75 325, which was compared with OAOII data⁶, and data from ANS and TD1 S2/68 (P. R. Wesselius and D. J. Carnochan respectively, personal communications); HZ43, for which ANS data are available⁹; and HD137389, which has been observed by the S2/68 instrument¹⁰. The calibration for the stars listed by Boggess *et al.*¹ was converted to the S2/68 scale using the correction factors given by Beeckmans³.

For the SWR camera, calibration curves obtained from the individual stars were averaged, giving double weight to the results for BD+75 325 and HZ43. The mean calibration curve so obtained was used for the reduction of all SWR extragalactic images. When compared with that given by Boggess *et al.*¹ this calibration curve shows two differences: the sensitivity minimum around $\lambda 1550$ is less pronounced, reflecting the difference between the OAOII and S2/68 or ANS flux scale (our continuum fluxes no longer have the $\lambda 1550$ hump), and the sensitivity at all wavelengths is lower. The extent of the second is comparable with the difference found by Boggess *et al.*¹ between the sensitivities obtained, after camera reoptimisation, for μ Col and HD60753. The four stars analysed for the SWR calibration all give roughly the same wavelength dependence for the sensitivity but the individual stars give absolute calibrations different by up to $\pm 20\%$ from the mean curve. Thus, the slope of a spectrum is well defined, but the overall flux level could be in error by $\pm 20\%$, in addition to any errors in the OAOII, S2/68

Table 1 Journal of observations

Date (1978)	Object	Camera,* band	Exposure (min)	Comments

or ANS calibrations and the errors involved in the transformation of the IUE data to other calibration systems (the latter is estimated to be ~10% for well-exposed spectra¹).

For the long wavelength cameras the high priority stellar targets permitted only a rough check for $2,000 \leq \lambda \leq 2,540$. For the accuracy of the measurements the results agree with the standard calibration¹, and this was used for the reduction of the objects in this paper.

Finally, we note that the 20% error mentioned above applies to both the short- and long-wavelength cameras, and the present results for the interstellar absorption maximum near $\lambda 2200$, which has to be measured on both the long and the short wavelength spectra for objects of low redshift, and is also subject to extra noise and uncertain end effects, should be treated as preliminary only.

NGC4151

Comprehensive reviews of observational results and model computations for Seyfert galaxies are given by Weedman¹¹ and Collin-Souffrin⁶⁶. The well-known Seyfert galaxy NGC4151 is the brightest of the class with broad permitted emission lines (Class 1 of Khachikyan and Weedman¹²) in the northern skies and has been closely studied at all available wavelengths. The permitted lines also contain a distinct narrow component with the same profile as the forbidden lines (which are always relatively narrow in Seyfert galaxies) and NGC4151 is better classified 1.5. Its nucleus contains a compact source which is variable at X-ray, UV, optical and IR wavelengths^{13-17,49}. It is also a γ -ray source¹⁸ and a weak source of radio emission¹⁹, although the radio emitting volume may be different from the region producing the optical continuum and broad emission lines²⁰. Recently an UV spectrum of NGC4151 has been obtained by Davidsen and Hartig with a rocket-borne telescope⁴⁶.

The optical spectrum of NGC4151 has been discussed by several authors²¹⁻²⁵. The narrow-line region has temperature $T = (11,750 \pm 800)\text{K}$, and electron density $N_e = 2 \times 10^4 \text{ cm}^{-3}$ in a higher ionisation region and $N_e = 5 \times 10^3 \text{ cm}^{-3}$ in a lower ionisation zone defined by [O I], [O II] and [S II], which will be excited at the outer portions of the gas²⁴. The relative intensities of the forbidden lines can be well matched by photo-ionisation models in which the gas is ionised by a non-thermal UV continuum, and probably this is also the main energy source for the broad-line region^{26,27}. The broad-line region is characterised by the permitted emission lines of H I, He I, He II and Fe II, and must have $N_e \geq 10^8 \text{ cm}^{-3}$ to collisionally de-excite the forbidden lines which are absent^{28,24}. High column densities are also indicated by the Balmer decrement, which can be understood

only if the higher Balmer lines are optically thick^{22,23,39}. As is commonly observed in such objects, the broad components of the Balmer lines in NGC4151 are asymmetric and extend over several thousand km s^{-1} ; the He II $\lambda 4686$ profile is similar, but He I $\lambda \lambda 5876$ and 7065 are much broader²⁴. The asymmetries and different linewidths rule out electron scattering as the dominant broadening mechanism, and invalidate the model for the line emitting region developed by Ptak and Stoner^{29,24}. There is now little doubt that the broadening is chiefly due to mass motions of the ionised gas in such active nuclei^{27,30,31}.

A striking feature of the optical spectrum of NGC4151 is the presence of non-stellar Balmer and He I $\lambda 3889$ absorption features which are blueshifted with respect to the emission lines and variable in time^{32,33,25,140}. These features are characteristically different from the absorption lines generally present in QSO spectra, which arise only from ground-state transitions and have never been seen to vary. Galactic interstellar Ca II absorption is also present in the spectrum of NGC4151 (refs 24, 25, 140).

NGC4151 was observed by IUE with both the short and long wavelength cameras (Table 1). The better exposed of the two short wavelength spectra (28 February) is shown in Fig. 2. Emission features (28 February for short wavelength, 11 February for long) are listed in Table 2 and the absorption features (28 February) in Table 3. Optical spectra taken soon after (8 March) (J. McClintock, personal communication) show that the visual absorption lines were particularly strong. For the absorption lines arising from levels of the ground state there is probably a significant galactic interstellar contribution in some cases (the heliocentric velocity of NGC4151 determined from the emission lines is about 950 km s^{-1} (ref. 32), and the absorption lines are blueshifted relative to NGC4151 by a comparable amount^{32,140}, bringing them to near-zero velocity in the observed frame).

The continuous spectrum of NGC4151 obtained on 28 February, with measurements averaged over bands 20–100 Å wide avoiding the emission and absorption lines, is shown in Fig. 3. We include our UBVI photometry (7 March), corrected for the emission lines and Balmer-continuum emission (the latter from the expression given by Stein and Weedman³⁴) and reduced to the same effective aperture as the IUE observations (10" × 20") from the data of Penston *et al.*¹⁶. We also show the continuum data of Davidsen and Hartig⁴⁶, obtained on 10 February.

The observed optical continuum of an active galaxy nucleus is made up of two parts: the featureless non-thermal or 'power law' continuum unique to the active nucleus, and the integrated galaxy continuum (containing absorption lines) due to stars in or near the nucleus. (The term 'non-thermal' is used rather loosely; 'non-stellar' might be better in some cases where a thermal source, possibly complex, cannot be ruled out.) When the continuum shows variability the spectral slope generally also varies due to the differing contributions of the non-thermal variable component and the stellar component, although the slope of the non-thermal component probably does not change¹⁴. Assuming a power-law spectrum of form $F_\nu \propto \nu^{-\alpha}$ we

Fig. 1 Photographic reproductions of unprocessed short wavelength spectra of four of the extragalactic objects: first, the Seyfert 1.5 galaxy NGC4151; second the Seyfert 2 galaxy NGC1068; third the QSO 3C273; fourth the BL Lac object B2 1101 + 38 (Markarian 421). Wavelength increases to the right. The large emission feature at the left of each spectrum is geocoronal Ly α which fills the 10 × 20 arc s entrance aperture.

The different degrees of reddening obtained for the continuum and forbidden line regions is interesting because it shows that our view of the continuum source is relatively unobscured by line-emitting gas, which therefore does not totally surround the continuum source. However, a covering factor as little as 0.7 is consistent with the observed strength of H β and our far UV continuum slope. A model of the ionised gas in Seyfert nuclei deduced from observational data is given by Osterbrock²⁷. We return to this later.

The spectrum of NGC4151 shows strong emission lines of Ly α , C IV λ 1550, He II λ 1640, C III] λ 1909, [O III]+C II] λ 2324, [Ne IV] λ 2424 and Mg II λ 2800, and several weaker lines (Fig. 2 and Table 2). There is little evidence of N V λ 1240, Si II λ 1263, O I λ 1305, C II λ 1335 or Si IV+O IV] λ 1400 in emission, but for these the spectrum is confused by definite or possible absorption features. Nevertheless, N V λ 1240, if present, is very weak. The presence of [Fe XI] λ 2650 is consistent with the detection of the coronal line [Fe XI] λ 7892 in this object⁴⁵.

The Ly α profile is affected by the geocoronal emission, a fiducial mark (reseau) and Ly α and N V absorption, but it seems to have comparable width to the Balmer lines²⁴. The C IV profile also is strongly affected by absorption, which makes it difficult to determine the FWHM, but it seems peculiarly broad with very extensive wings. Accounting for contributions from N IV] λ 1486, [Ne IV] λ 1602 and possibly [Ne V] λ 1575 still leaves a very broad asymmetric line of full width at zero intensity $\approx 15,000$ km s⁻¹, which is comparable with the broad He I lines observed in the visible²⁴ and suggests a common origin. Alternatively, there may be a strong contribution from Fe III to the C IV profile, as contended by Davidsen and Hartig⁴⁶, but

Fig. 3 NGC4151 continuum fluxes (28 February 1978 for SW, 11 February 1978 for LW, see Table 1). The IUE data are averaged over bands 20–100 Å avoiding the emission lines. Our UVB photometry (6 March 1978) reduced to the IUE observing aperture, also are corrected for emission lines (■) and additionally for Balmer continuum emission (□). The continuum data of Davidsen and Hartig⁴⁶, obtained on 10 February 1978, are included. The error bars indicate 1 σ statistical uncertainties in signal only, and do not include possible calibration errors. No reddening correction is applied.

according to the results of Viotti⁴⁷ Fe III emission around λ 1550 should be accompanied by even stronger Fe III emission between $\lambda\lambda$ 1840 and 2020, which is absent in our data. In contrast, C III] λ 1909 is relatively narrow, but a broad component of comparable width to that of the Balmer lines is clearly present, blended with Si III] λ 1892 in the blue wing. This sets an upper limit of $N_e \leq 10^{10}$ cm⁻³ to the broad-line region.

Netzer³⁹ has shown that a steep Balmer decrement can be produced if $N_e > 10^8$ cm⁻³, in explanation of observed inconsistencies when attempting to fit extinction-corrected Balmer line strengths for QSO and Seyfert galaxies to values predicted from radiative recombination theory. Baldwin⁴⁰ has pointed out a more extreme difficulty for the intensity ratio of Ly α to H β in QSOs, which is directly observed or deduced to be ≈ 3 (refs 40–42). Recombination theory predicts values 22–40 depending on the extent that Ly α is collisionally excited. While selective extinction by dust could reduce the relative intensity of Ly α , particularly if it has a large optical depth compared to H β and is multiply scattered, it is curious that $I(\text{Ly}\alpha)/I(\text{H}\beta)$ is so remarkably constant among cases having substantially different apparent reddening. This matter has been further discussed recently by Zirin⁴⁰. For the Seyfert galaxy NGC4151, also, we find $I(\text{Ly}\alpha)/I(\text{H}\beta) = 4.4 \pm 2$ using $I(\text{H}\beta) = 6.6 \times 10^{-12}$ erg cm⁻² s⁻¹ (refs 21, 22, 24). Assuming that $E(B-V) = 0.6$ holds not only for the continuum but also for the permitted line region (which emits most of the flux in the hydrogen lines), and making a simple application of the same extinction law as before, gives $I(\text{Ly}\alpha)/I(\text{H}\beta) = 6.3 \pm 3$. On the other hand, if $E(B-V) = 0.24$, as deduced for the narrow-line region from the [S II] lines, we obtain $I(\text{Ly}\alpha)/I(\text{H}\beta) = 18 \pm 8$, closer to the recombination value. Note that the presence of geocoronal Ly α , Ly α absorption in the Galaxy and in NGC4151, and the camera fiducial mark in the red wing of the NGC4151 Ly α line makes the measurement of this line rather uncertain.

Baldwin⁴³ has found that for QSOs there exists an important correlation between $W_{\lambda_0}(\text{C IV})$, the rest frame equivalent width of the C IV λ 1549 emission doublet, and $L_{\nu}(1450)$, the continuum luminosity at a rest wavelength λ 1450 computed on the assumption that the redshift is a cosmological indicator of distance, suggesting that these objects can be used as standard candles. The relationship seems particularly tight if restricted only to the flat spectrum radio sources, as confirmed by Baldwin *et al.*⁴⁸. The similar study by Omer⁴⁴ is in apparent conflict, showing $W_{\lambda_0}(\text{C IV})$ to be independent of $L_{\nu}(1475)$, but he covered a smaller luminosity range and his results are consistent with Baldwin's more widely ranging data. Comparing our (rather uncertain) value of $W_{\lambda_0}(\text{C IV})$ for NGC4151 with

Table 3 Absorption lines in the spectrum of NGC4151 ($\lambda < 2,000$, 28 February spectrum; $\lambda > 2,000$, 11 February spectrum)

*Wavelength measured relative to other known lines.

†The unknown contribution of the emission lines to the local 'continuum' for the absorption lines makes the values of equivalent width for these uncertain.

Fig. 4 Short wavelength spectrum of the Seyfert 2 galaxy NGC1068, photometrically corrected and calibrated. Emission lines are indicated, including suspect and apparent unidentified features. The Ly α line is saturated, and contaminated by geocoronal Ly α . The almost complete separation of Ly α and NV is real, not due to the fortuitous presence of the reseau (see Fig. 1).

Baldwin's relationship gives an expected luminosity $\log L_v(1450) = 30.1$, but we find the value 27.9, which is in serious conflict. Later we shall show the Seyfert galaxy NGC1068 and the BL Lac object B2 1101 + 38 (which is a flat spectrum radio source) also do not fit the relationship but the QSO 3C273 does fit well. We conclude that Baldwin's luminosity relationship at least is not generally applicable to active nuclei, and with the available evidence seems to segregate QSOs from Seyfert galaxies and (less surprisingly) BL Lac objects. However, excluding B2 1101 + 38, we note that over the large luminosity range now obtaining with the inclusion of NGC4151 and NGC1068 with the sample of QSOs, the data broadly conform with Osmer's⁴⁴ results which show no luminosity dependence for W_{λ_0} (C IV).

From model computations Shields⁵¹ has shown that use of some of the weaker emission lines allows abundance determinations that are not strongly dependent on the details of the photoionisation models for active nuclei; in particular, these are: O III] λ 1663, N IV] λ 1486, N III] λ 1749 and C III] λ 1909. Baldwin and Netzer⁵² made a refined analysis and find some minor modifications to Shield's results. Using Shield's relationships we find the relative abundance N/C is 0.16 from N IV]/C IV and 0.13 from N III]/C III]. Baldwin and Netzer⁵² find N III]/C III] is ~ 1.5 larger in their analysis, and using their correction we obtain N/C = 0.09. For O/C and N/O we obtain 1.37 and 0.20 from use of O III]/C IV and N IV]/O III] respectively. Given the uncertainties in our line fluxes, these values are reasonably self-consistent and give relative abundances N/C/O which are comparable with solar values¹⁴¹.

Our two short wavelength spectra were obtained 17 d apart (Table 1). Although the 11 February exposure is somewhat out of focus and underexposed, there is clear absorption present at C IV λ 1550, Si IV $\lambda\lambda$ 1394, 1403 and C II $\lambda\lambda$ 1335, 1336. If N V λ 1240 is present it is rather weak. Our well-exposed and in-focus spectrum of 28 February shows the several lines listed in Table 3. N V is strong, C II seems weaker, and C IV stronger with the absorption more centrally placed in the emission line, than on 11 February. C II seems rather diffuse (28 February spectrum), contrasting with the sharp Si IV and Si II lines. Time-varying structural differences between the He I λ 3888 and Balmer line absorption features have been observed in the optical spectrum^{141,32}. In the spectrum obtained by Davidsen and Hartig⁴⁶ one day earlier than our first spectrum, N V, Si IV

and C IV seem absent, Si II and C II are strong, and there may be other features. Their resolution is lower than ours, and C IV, for example, may be present but lost in the strong emission profile. However, at face value there is evidence that the ionisation of the absorption system has changed greatly over the period of 18 d between the observations of Davidsen and Hartig and our good 28 February spectrum, and to some degree in the one day between their observation and ours of 11 February. Some change in line strength is evident over 17 d from the IUE data alone. The dramatic increase in ionisation apparent from the time of Davidsen and Hartig's observations is accompanied by a large increase in the far UV continuum flux discussed earlier, if real.

The presence of the C III* λ 1176 absorption line, which arises from the metastable $2p^3P^0$ state, is consistent with the excitation of the optical spectrum^{25,32,140}. Si II* λ 1265 arises from an excited fine structure level, and seems comparable in strength to the ground state line λ 1260, suggesting that the electron density in the absorbing region is $N_e > 10^4 \text{ cm}^{-3}$ if the level is populated by collisions at $T_e \approx 10^4 \text{ K}$. However, the Si II lines are only marginally detected.

At our relatively low resolution we cannot determine the true depth of the absorption lines, but it is clear from the observed depths of the various strong absorption features that not only the continuum but also a substantial fraction of the broad-line-emitting region is covered by the absorber. Thus, the absorbing region cannot be a component (filament) of the broad-line-emitting region but must be more extensive and outside it. A similar conclusion was reached by Anderson³² from the optical data.

NGC1068

NGC1068 is the archetype of class 2 Seyfert galaxies, and has been well studied at optical, IR and radio wavelengths^{16,20,54-63,68}; it shows no convincing variability. It has an IR nucleus $\sim 100 \text{ pc}$ in diameter, which is inconsistent with a single non-thermal source, but is consistent with emission from heated dust⁵⁸. Emission features due to H₂ are present in the IR spectrum⁶², and the absorption feature near $9.5 \mu\text{m}$ which has been attributed to silicates is strong⁶⁴. It has somewhat broader lines than other Seyfert 2 galaxies, with FWHM about $1,200 \text{ km s}^{-1}$, but they are still considerably narrower than in Seyfert 1 galaxies. The lines have an asymmetric form with much velocity structure, and spatial structure discernible on a scale of $1''$ or 70 pc (ref. 65) and extending over $\sim 8''$ (ref. 59). The line emitting region is physically complicated, having regions of different density, filling factor and degree of shadowing from the continuum source^{57,56}. NGC1068 is another of several Seyfert galaxies found to emit the coronal line [Fe XI] λ 7892 (ref. 45).

NGC1068 was observed by IUE only with the short wavelength camera. The spectrum is shown in Fig. 4. Only emission features are definitely observed, and these are listed in Table 4. The spectrum was over-exposed in Ly α , and this line

*Wavelength measured relative to other known lines

†Uncertain.

also is contaminated by the geocoronal emission, so we have no reliable flux estimate. The almost complete separation of Ly α and N V λ 1240 is real, not due to the fortuitous presence of the *resseau* (see Fig. 1).

Continuum fluxes, mostly averaged over about 40Å and avoiding the emission lines, are shown in Fig. 5, together with part of Wampler's⁵³ spectrophotometry also avoiding emission lines and reduced to the IUE observing aperture with the aid of the data of Penston *et al.*¹⁶. We find $\alpha = 2.4$ fitted to the usual power law as a mean over the whole optical and UV region included in Fig. 5. With our aperture, the visual flux of the nuclear source is much weaker than that of the underlying galaxy^{16,69} but in the far UV (IUE) region, where contamination from the galactic component is negligible, we obtain the important result that the continuum clearly is a power-law spectrum, with $\alpha \approx 1.8$ (not accounting for reddening); there is no unambiguous evidence of a power-law continuum in the optical region. We have no direct estimate of reddening from the IUE data (the region containing the λ 2200 absorption feature was not observed) but if we apply a correction based on the value $E(B-V) = 0.5$ derived from the [S II] lines and the Balmer decrement^{55,67} the resulting spectrum is highly inconsistent with a power law continuum, suggesting that $E(B-V)$ for the continuum is much smaller (≤ 0.15) and implying $\alpha \geq 1.4$. However, a flatter continuum than observed may be needed to explain the presence of [Fe XI] (ref. 45) and the observed value of $I(\text{He}^+)/I(\text{H}^0)$ (ref. 57).

The different degrees of reddening deduced for the continuum and emission line regions again shows that the continuum is not completely surrounded by line-emitting gas. This is consistent with optical and radio data^{57,61}.

The spectrum of NGC1068 shows strong, relatively narrow, emission lines of Ly α , N V λ 1240, C IV λ 1550, He II λ 1640 and C III] λ 1908 (Fig. 4 and Table 4). Several weaker lines are definitely present, including Si IV + O IV] λ 1400, N IV] λ 1486 and N III] λ 1749.

Comparing our value of W_{λ_0} (C IV) for NGC1068 with Baldwin's⁴³ empirical relationship coupling this quantity with

Fig. 5 NGC1068 continuum fluxes. The IUE data are averaged over about 40Å bands. Wampler's⁵³ spectrophotometry is reduced to the IUE observing aperture. Both sets of data are chosen to avoid emission lines. The error bars indicate 1 σ statistical uncertainties only. No reddening correction is applied.

Fig. 6. Short wavelength spectrum of the QSO 3C273, photometrically corrected and calibrated. Emission and absorption lines are indicated (see related comments in the caption to Fig. 2)

$L_p(1450)$, as we have done for NGC4151, gives an expected luminosity $\log L_p(1450) = 30.1$, but we again find a much lower value, 27.4. Thus, we find serious (and similar) departures from Baldwin's relationship for both the Seyfert galaxies studied here.

Calculating the relative abundance N/C from the work of Shields⁵¹ and Baldwin and Netzer⁵², as before, we find the value ~ 1.0 , nearly six times the solar value¹⁴¹. Shields and Oke⁵⁷ find a fourfold over-abundance for N/O from optical data for this object.

3C273

Like the other bright extragalactic objects discussed here the QSO 3C273 ($z_{\text{em}} = 0.158$) has been very well studied at all available wavelengths^{70-80,82,58}. Far UV observations preceding the present work were made by Wu⁸ and Davidsen *et al.*⁴². Apart from being the brightest QSO, 3C273 is also one of the most luminous. It is only moderately variable in the radio, IR, optical and X-ray regions^{54,79}. VLBI radio measurements indicate a double component apparently separating at a projected linear velocity $\sim 4c$ (ref. 80). 3C273 is among comparatively few QSOs which show the forbidden lines to be very weak, indicating that there is very little low density gas in the line-emitting region⁷⁵. It is also rare in showing strong Fe II emission^{72-75,81}.

3C273 was observed by IUE with both spectrograph cameras, as detailed in Table 1. One of the two short wavelength spectra is shown in Fig. 6. Emission features are listed in Table 5. Weak absorption features are also present, listed in Table 6, but are not easy to discern in Fig. 6 because at this time the telescope focus was rather soft (in Fig. 1 compare the raw spectrum of 3C273 with that of NGC4151 which was in sharp focus, although trailed). We identify all but one doubtful line as arising in interstellar gas in the Galaxy. Corresponding hydrogen absorption at Ly α is not observed, but this region is masked by geocoronal Ly α emission as a consequence of using the large entrance aperture.

The continuous spectrum of 3C273, with measurements averaged over bands 20–50Å wide avoiding the emission lines, is shown in Fig. 7. We include our UBV photometry, and Wu's⁸ ANS photometry, both corrected for emission lines, and the continuum data of Davidsen *et al.*⁴². Assuming the usual power law we find $\alpha \approx 1.0$ for the slope of the continuum over our whole observed UV (IUE) range, uncorrected for possible reddening. In optical range, as is well known^{42,75}, the spectrum is much flatter and contains strong Balmer continuum emission (in the U- and B-channel). Davidsen *et al.*⁴² argue that for 3C273 there is no internal reddening and for galactic reddening they deduce $E(B-V) = 0.01$; but Wu⁸ estimates $E(B-V) = 0.07$ for galactic reddening, and from an apparent absorption at redshifted λ 2200 obtains $E(B-V) = 0.13$ for internal reddening. At least for the line emitting region, internal reddening is

Fig. 7 3C273 continuum fluxes. The IUE data are averaged over bands 20–50 Å wide avoiding the emission lines. Our UBV photometry and the ANS photometry⁸ also are corrected for emission lines. The continuum data of Davidson *et al.*⁴² are included. No reddening correction is applied. The error bars indicate 1σ statistical uncertainties only. Although the various observations were not made concurrently, we may rely on the general character of these continuum data as 3C273 is known not to be highly variable.

suggested by the observed Balmer decrement, which is steeper than the predicted recombination values and perhaps indicates $E(B - V) = 0.69$ (ref. 75), although reddening alone does not seem a sufficient explanation⁷¹. However, reddening is not confirmed by the ratio $Pa/H\alpha$ (ref. 83), nor the helium line strengths⁷⁵, showing that the situation is more complicated than supposed^{75,73,39}. The IUE spectrum is somewhat contaminated near the redshifted position of the $\lambda 2200$ dust feature, but there is no sign at all of broad absorption at this wavelength, and on this basis we conclude that internal reddening is small for the 3C273 continuum.

3C273 shows strong line emission at $Ly\alpha$ and C IV $\lambda 1550$, moderate emission at $Ly\beta + OVI \lambda 1035$, N V $\lambda 1240$, Si IV + O IV $\lambda 1400$, C III $\lambda 1909$ and Mg II $\lambda 2800$, and has some definite or possible weaker lines, as shown in Fig. 6 and Table 5. There is no obvious difference between the UV emission line spectrum of 3C273 and those of high redshift QSOs observed optically^{52,85,86,44}, except that C III $\lambda 1909$ seems weaker than average, suggesting a relatively high density in the line emitting region. The ratio of line strengths $I(N V \lambda 1240)/I(Ly)$, ~ 0.09 , is within the range observed for high redshift QSOs, which show a wide variation in this ratio^{44,52,86,87}. Once more we find that the ratio $I(Ly\alpha)/I(H\beta)$ is much lower than predicted by recombination theory; combining our measurement of the $Ly\alpha$ flux with the value obtained by Davidson *et al.*⁴² and comparing this with previous measurements of the $H\beta$ flux^{75,84} gives $I(Ly\alpha)/I(H\beta) = 5.5 \pm 2$. Again we note the remarkable constancy of the observed ratio. Assuming no reddening in the line-emitting region but applying Wu's⁸ galactic reddening correction raises the ratio to 7 ± 3 ; using the smaller correction of Davidson *et al.*⁴² gives the value 6 ± 2 .

Comparing our value of $W_{\lambda 0}$ (C IV) for 3C273 with Baldwin's⁴³ luminosity relationship, as before, gives an expected

luminosity $\log F_{\nu}(1450) = 30.6$. Our observed value is 31.0, in good agreement. As already stated, with the available evidence the range of validity of Baldwin's relationship among active nuclei seems to be restricted to QSOs. Baldwin's result is not expected from simple photoionisation models which naturally lead to a constancy of equivalent width with luminosity, as found by Osmer⁴⁴: for a given spectral index the continuum flux is an indicator of the energy available for heating the gas and the C IV line is a good measure of the energy emitted by the gas; hence the equivalent width, that is, the line strength expressed in terms of the continuum, should be independent of luminosity. However, Osmer⁴⁴ does find a significant luminosity dependence for $W_{\lambda 0}(Ly\alpha)$, also noted by Baldwin⁴³, to an extent not expected in the photoionisation model.

The optical Fe II emission lines in 3C273 all arise from transitions between odd-parity levels at ~ 5 eV and even-parity levels at ~ 3 eV (refs 82, 113). The transitions from these 3 eV levels down to the lower-lying levels of the ground state are forbidden. These [Fe II] transitions are not observed in 3C273, indicating that the electron density $N_e > 10^7 \text{ cm}^{-3}$ in the Fe II emission region. The most likely mechanisms for producing the observed Fe II emission are resonance fluorescence of continuum radiation¹¹³ and collisional excitation^{78,82,114,115}, the former being the one generally preferred although the correlations implied by this mechanism are not observed¹⁴². The strongest Fe II lines in 3C273 belong to multiplet 42 ($\lambda\lambda 4924, 5018$ and 5169). A test of resonance fluorescence is to observe the spectral region of the resonance lines in multiplet 3UV (around $\lambda_0 2340$) and look for absorption of continuum photons¹¹⁶. No such absorption is observed for 3C273. (Fe II absorption lines are present in NGC4151, which also shows weak optical Fe II emission, but these are most likely in part due to the unusual absorbing region observed in this object and in part galactic). Model calculations^{82,113} imply nearly complete conversion of the UV continuum to explain the strength of the optical Fe II emission, so it is surprising that no obvious absorption is present. On the other hand, collisional models predict strong emission in the resonance lines⁸², which also is not observed. In fact, the fluorescence models also predict strong resonance line emission, complementing the continuum absorption in the same lines. Depending on the geometry of the line-emitting region, fluorescence models could produce either net absorption or emission in the resonance lines, so the failure to observe either does not rule out the mechanism⁸². Again, collisional models imply a very large optical depth in the resonance lines⁸² and substantially all resonance photons may then be destroyed through the leak which gives the optical lines. The effect of increasing optical depth has been discussed by Jordan¹⁴³. But then resonance fluorescence of continuum radiation would also occur, so collisional excitation alone is not likely

to be responsible for the strong optical Fe II emission. Detailed model predictions are required to resolve this question. (See note added in proof.)

The very efficient conversion of the UV continuum into optical emission required if resonance fluorescence is the principle excitation mechanism implies 0.5–1.0 of the sky as seen from the continuum source is covered by optically-thick clouds⁸². This conclusion also seems consistent with the large equivalent width of H β generally observed^{40,82}. However, we would then expect $W_{\lambda_0}(\text{Ly}\alpha) \approx 700 \text{ Å}$ for a continuum slope $\alpha = 1^{40}$, but the observed values, as for 3C273, are about an order of magnitude smaller. The known general absence of Lyman continuum absorption in the rest frame of high redshift QSOs⁸⁶ implies that <0.1 of the continuum radiation is intercepted by optically thick clouds. This is consistent with the observed Ly α equivalent widths (if Ly α has not been strongly attenuated) and also with model calculations embodying other UV lines observed in high redshift QSOs⁵², yet is inconsistent with the H β (and Fe II) strengths which become anomalously high for a covering factor <0.1 .

Narrow absorption lines resembling the interstellar lines of our Galaxy are frequently observed in the spectra of QSOs and BL Lac objects. In general, these lines may be grouped into one or more systems corresponding with the apparent wavelengths of transitions in a physically plausible group of atoms or ions exhibiting the same, although arbitrary, redshift^{88,89}. Such absorption systems range in redshift from being comparable with the associated emission line redshift, to having very much smaller values which in some cases give a velocity relative to the QSO exceeding 0.6c. The general character of the absorption lines does not seem to differ for systems widely ranging in redshift, and velocity relative to the QSO. However, for QSOs of sufficient redshift to bring the Ly α emission line into the observable optical range, it is striking that most of the absorption lines fall shortwards of Ly α emission, and that the bulk of these cannot be grouped into convincing absorption systems. It is generally accepted that these unidentified lines represent Ly α absorption in gas extending to lower redshifts than the QSO against which they are observed and for which lines of other elements are too weak to be detected⁹⁰. In support of this is the frequent identification in these cases of one or more other members of the Lyman series^{91,92}.

The question of the origin of QSO absorption lines has been greatly discussed^{7,93–106}. In principle, the narrow-line absorbing regions may be intrinsic to the QSOs, having been somehow ejected at velocities up to the very high values observed, or they may be cosmologically distributed in direct association with galaxies or as intergalactic clouds. The outflow hypothesis has several difficulties, principally the implication of implausibly large mass and momentum flow relative to the QSO^{97–100}, and the balance of evidence now strongly favours the cosmological hypothesis. On the other hand, the very broad-line absorption present in some QSOs is probably intrinsic⁷.

From the observed frequency of absorption systems containing heavy elements, if related to galaxies, the effective size of a galaxy seen in absorption must be several times its arbitrary Holmberg dimensions^{7,94,106,107}. However, as pointed out by Bahcall and Spitzer¹⁰⁸ the gas density required to produce absorption lines is so low that it would not be surprising if the maximum dimensions for measurable absorption in a line were much greater than the dimensions detected in other ways, and they suggested that the observed lines could be produced in

extended low density haloes of normal galaxies. Direct evidence that heavy element absorption lines in QSO spectra can be caused by the interception of the outer regions of spiral galaxies well outside the Holmberg dimensions comes from the detection by Boksenberg and Sargent¹⁰⁹ of Ca II absorption lines in the spectrum of the QSO 3C232 ($z_{\text{em}} = 0.5303$) at the same redshift as the galaxy NGC3067 which lies 1.9 arc min away in the plane of the sky, or about 1.5 Holmberg radii (using $H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$), following the discovery by Haschick and Burke¹¹⁰ of H21 cm absorption in this system. Taking into account the inclination of NGC3067, the line of sight intersects the plane of the galaxy at a radial distance greater than 6 Holmberg radii out from the centre. However, the characteristics of the absorption system point to it arising in the outer halo of NGC3067 not the disk extension¹⁰⁹.

For 3C273 we find absorption lines only at zero redshift (Table 6), presumably arising in our Galaxy. Corresponding galactic Ca II absorption has been reported by Greenstein¹¹¹. Wagoner¹¹² has computed the probability that light received from a distant QSO be intercepted by an intervening galaxy and show absorption lines. Assuming an effective cross-section 10 times the area defined by the Holmberg dimensions, Wagoner's data still give only 0.05 as the probability of interception along the line of sight to 3C273, which is consistent with our null detection. This further supports the cosmological hypothesis for the absorbing material. On the outflow hypothesis the probability of detecting absorption systems is not expected to depend strongly on the redshift of the QSO.

Turning to the consideration of the Ly α absorption lines normally seen optically in the spectra of high redshift QSOs, even if the resolution of our 3C273 spectrum were not sufficient to separate these lines, if present, we would expect them to blend into a marked depression of the apparent continuum shortwards of Ly α emission. Neither we nor Davidsson *et al.*⁴² observe such a depression. The observed number density of the Ly α absorption lines seems to increase quite rapidly with redshift, with objects of $z_{\text{em}} \sim 2$ showing a markedly lower absorption line density than those of $z_{\text{em}} \sim 3$. Our null detection for 3C273 follows this trend and again supports the cosmological hypothesis. There is

Fig. 8 B2 1101+38 continuum fluxes. The IUE data are averaged over 50 Å bands. The UBVI photometry are approximately concurrent with the IUE measurements (see Table 1). Errors are estimated only from the 1 σ statistical uncertainty in signal. No reddening correction is applied.

Fig. 9 Spectrophotometry and photometry of the central region of the spiral galaxy M81. The IUE short wavelength measurements are averaged over 100 Å bands. The errors define 1σ statistical uncertainties in signal only. The BV photometry (from ref. 127) and the narrow band photometry are reduced to the IUE observing aperture. The data are de-reddened using $E(B-V) = 0.06$. The derivation of the calculated fluxes is described in the text.

evidence that the Lyα absorption systems represent in part very extended outer regions of galaxies where the density is too low to allow star formation and the gas still has primordial composition, and in part truly intergalactic gas not bound to galaxies⁷.

B2 1101+38

B2 1101+38 (= Markarian 421) is a radio-faint galaxy¹¹⁷ identified as a BL Lac object^{118,119} and also is an X-ray source^{120,144}. It is among a few BL Lac objects observed to be surrounded by a nebulosity. Three absorption features in the spectrum of the nebulosity are consistent with being Ca II K, H and the G-band at $z = 0.03$ (refs 118, 121) and may be interpreted as originating from the main body of an elliptical galaxy having an extremely bright nucleus. BL Lacertae itself is similar, with $z = 0.07$ (refs 122–125). Five galaxies within 15' of B2 1101+38 are found also to have $z = 0.03$, showing that this object belongs to a cluster of galaxies¹²¹.

BL Lacertae objects in general appear similar to variable QSOs except that they lack strong optical emission lines. For a review of BL Lac objects see Stein *et al.*¹²⁶. Attempts to explain the absence of emission lines are usually based on (1) the supposition of a lack of UV photons to ionise a surrounding gas; (2) the absence of any such gas; or (3) a combination of both.

In our extension into the far UV there are still no emission-lines evident in the spectrum of B2 1101+38. There is, however, a strong non-thermal continuum. In Fig. 8 we show the IUE continuum measurements and include our UBVI photometry (see Table 1). Assuming a power law spectrum of the usual form $F_\nu \propto \nu^{-\alpha}$ we obtain $\alpha = 1.2$ as a mean value over the observed range. The radio spectrum is flatter, with $\alpha = 0.26$. As there is no sign of Lyα absorption at $z = 0.03$ (which would be clear of the geocoronal Lyα emission) we may assume that the observed UV spectrum extends well into the Lyman continuum. This is supported by the measurements of the possible X-ray counterpart by Ricketts *et al.*¹²⁰ which indicate a steady component of 0.7 Ariel 5 count s⁻¹ (sometimes brightening by up to a factor 20) while extrapolation of our continuum predicts 0.5 counts s⁻¹. There may be slight reddening, as our data are too noisy to confirm the absence of a weak absorption feature at local or redshifted λ 2200, but there is no strong reddening so indicated.

If photoionisation is the source of line emission we may calculate the equivalent width of Hβ in terms of the photoionising continuum, assuming that the gas which gives rise to line emission is optically thick and completely surrounds the

continuum source. Using the expression given by Penston and Fosbury⁸⁴ (taking a continuum high-frequency cutoff at λ 228) we obtain $W_\lambda(H\beta) \approx 50 \text{ Å}$ for $\alpha = 1.20$. (There is an omission in their expression as given; the correct expression is

$$W_\lambda(H\beta) \approx 564 \left(9.64 \frac{0.553}{K} \right)^{-\alpha} \left[\frac{K^{-\alpha} - 1}{\alpha} \right]$$

where $K = 0.553$ or 0.250 with the continuum high-frequency cutoff at λ 504 or λ 228 respectively, and α is defined above). If the intensity ratio of Lyα to Hβ is ≈ 3 , as is now commonly observed or deduced (see above) and using

$$I(\text{Ly}\alpha)/I(H\beta) = (4861/1216)^{-\alpha} W_\lambda(\text{Ly}\alpha)/W_\lambda(H\beta),$$

then $W_\lambda(\text{Ly}\alpha) \approx 50 \text{ Å}$. Our observed upper limit is $W_\lambda(\text{Ly}\alpha) \leq 10 \text{ Å}$. In the previous section we have discussed the conflicting evidence regarding complete (or nearly complete) coverage of the photoionising source. However, the Hβ strength normally observed in QSOs and Seyfert galaxies is well explained in this way. Thus we may conclude at least for B2 1101+38, and probably for BL Lac objects in general, that the absence of emission lines is due not to a deficiency of ionising flux, but of gas in the physical or geometrical state normally found in the line-emitting regions of low redshift QSOs. A similar conclusion follows from the lack of detectable X-ray absorption in such objects¹⁴⁴.

From Baldwin's⁴³ empirical relationship coupling $W_{\lambda_0}(\text{C IV})$ with $L_\nu(1450)$, discussed above for NGC4151, NGC1068 and 3C273, we expect from our continuum flux that $W_{\lambda_0}(\text{C IV}) = 590 \text{ Å}$, but our observed upper limit is $W_{\lambda_0}(\text{C IV}) \leq 15 \text{ Å}$. Again we have a serious departure from Baldwin's empirical relation; it is interesting that B2 1101+38 has a flat radio spectrum and Baldwin finds his correlation is particularly tight for QSOs with such spectra.

M81

The central region of the well-studied spiral galaxy M81 was observed only with the short wavelength spectrograph on IUE (Table 1). The signal obtained was low, and to increase the signal-to-noise ratio we binned the data into 100 Å bands, as shown in Fig. 9 which also shows the BV photometry of Brandt *et al.*¹²⁷ and the narrow band photometry of Spinrad and Taylor¹²⁸ and Peimbert¹²⁹. The Spinrad and Taylor results were normalised to Peimbert's at λ 5360. These are all reduced effectively to the same observing aperture as used for the IUE data. All the observed data are de-reddened using $E(B-V) = 0.06$ (ref. 128), and the extinction law of Code *et al.*³⁸ in the UV.

Fig. 10 Spectrophotometry and photometry of the central region of the giant elliptical galaxy M87. The long wavelength IUE data are averaged over 100 Å bands and include only 1σ statistical uncertainties in signal. The photometry are from refs 137 and 139 and are reduced to the IUE observing aperture. No reddening correction is applied.

We also show a theoretical extension of the optical data into the UV calculated from the stellar population of Spinrad and Taylor¹²² and the appropriate UV stellar fluxes from the TD1 S2/68 instrument¹⁰.

The observed IUE spectrum clearly does not arise from the assumed stellar population, whose emission is dominantly from G-type subgiants, but in magnitude agrees well with Peimbert's¹²⁹ estimate of the fluxes required from a hot star population (late O-type) needed to explain the intensity of the observed H α and [O III] emission in this object. However, our flux distribution has the wrong slope for Peimbert's assumed stellar population, and is fitted better by a mean A0 spectrum, but this will not be able to provide the required photoionising flux. Alternatively, the observations are well-explained by a non-thermal continuum source of spectral slope $\alpha = 2$. The radio nucleus of M81 is known to be variable and is about 10^4 times more luminous than the compact radio source at the galactic centre⁸⁰.

M87

The peculiar EO galaxy M87 (=NGC4486=Arp 152=3C274=Virgo A) is an active (core-halo) radio source with compact central components^{130,131}. It also has compact and extended X-ray emission¹³⁴⁻¹³⁶, and there is evidence for ejection of mass from the nucleus in the form of optical jets^{132,133}, and for a massive black hole in the nucleus^{137,138}.

M87 was observed by IUE only with the long wavelength spectrograph. Again we binned the data into 100Å bands to increase the signal-to-noise ratio. The results are shown in Fig. 10. We include BV photometry from de Vaucouleurs and Nieto¹³⁹ and Young *et al.*¹³⁷, reduced to the same observing aperture as for the IUE data.

From our UV data, an early G-type spectrum is indicated for the nuclear region of M87. Late G-type to early K-type (dominant in the visible flux) is too cool, as for this an absorption edge cuts off the flux below $\sim \lambda 2640$. F-type subgiants can be ruled out as the slope is wrong and the absorption dip at $\lambda 2400$ present in F-type stars¹⁰ is not evident in the IUE spectrum. Actually, there is marginal evidence for an emission peak (perhaps [Ne IV] $\lambda 2424$). There may also be some contribution from a non-thermal continuum, which is expected for this object.

We thank J. McClintock for optical spectra of NGC4151 and 3C273, P. R. Wessellius and D. J. Carnochan for results before publication, and D. C. Morton and J. B. Oke for helpful comments.

Note added in proof. Recent computations^{145,146} suggest observational evidence does point strongly to collisional excitation as the dominant mechanism producing Fe II optical emission lines

During the scientific commissioning phase of IUE several spectra were acquired from objects residing in the Solar System. The activities focused on testing numerous parameters which would indicate the usefulness of IUE for planetary science. It seems that IUE can successfully tackle many important questions and the data analysis and interpretation of the initial set of observations has begun.

IUE PROVIDES an excellent way for acquiring UV spectra in the wavelength region shortwards of the Earth's ozone cutoff (about 3,100 Å). The UV vidicons, when properly erased and prepared for use, can be exposed for several hours on very weak planetary emissions. This integration time, and the ability of the spacecraft to be adjusted to track on planets or their natural satellites for extended periods, combine to provide an overall capability which is well beyond the reach of sounding rockets. The low resolution channel (linear spectrum) has a spectral resolution of 7–8 Å FWHM, much like the classical rocket and satellite spectrometers now in use. The high resolution mode (echelle spectrum) gives a spectral resolution in the range 0.1–0.2 Å FWHM. (The scientific instrument is described by Boggess *et al.*¹) Either the large 10 × 20 arc s slot or the 3 arc s circular aperture can be used for studies requiring spatial resolution, if the tracking can be adjusted and maintained to ~ 1 arc s during an exposure. The sample spectra which were recorded during the IUE commissioning phase show some of the possibilities for future studies with Solar System objects. Table 1 represents the wide range of objects examined. The efforts centred around acquiring exposure times for reasonable signal-to-noise ratio spectra and becoming familiar with the IUE capability. No definitive study of any one object was performed, but an overall analysis of what further studies would be possible was accomplished.

Figure 1 reproduces a single long-wavelength spectrum of Mars, acquired through the small, 3 arc s aperture. Useable information is obtained down to 2,200 Å. The decrease in signal strength longwards of 2,900 Å is the result of the threshold of

the caesium telluride photocathode in the UV quantum converter which is in front of the vidicon faceplate. The spectrum was obtained by placing the small aperture over the 8 arc s diameter disk of Mars, and using the fine error sensor (FES) to lock onto the 'spill-over' light. The exposure was short enough (15 s) to not require trimming of the spacecraft gyros to the non-sidereal motion of Mars. The strong Mg I and Mg II solar absorption lines are easily detected at 2,852 and 2,795 and 2,802 Å, respectively. Just longwards of 2,900 Å, the spectrum saturated slightly, but the data became valid again at 2,960 Å. Although the signal is not strong in the 2,400–2,600 Å region, no pronounced absorption band is seen around 2,550 Å where the Hartley band system of ozone has its maximum absorption. If substantial ozone were present in the martian atmosphere, one would expect to see an absorption bowl in the Mars spectrum². To enhance the detectability, within the limits of the statistics of a single spectrum, the Mars spectrum was compared with a lunar spectrum also obtained with IUE. This is displayed in Fig. 2. No apparent minimum is observed and the slope of the ratio represents the albedo differences of the two bodies. The Mars spectrum was recorded while its northern hemisphere was in late spring ($L_s = 70^\circ$) and the north polar region was tipped towards Earth, substantially obscuring the south polar region. In

Table 1 Objects from the Solar System observed using IUE

Object	Wavelength range	Dispersion
Mars	Long	High and low
	Short	Low
Jupiter	Long	High and low
	Short	Low
Saturn	Long	Low
Uranus	Long	Low
	Short	Low
Io	Long	Low
Ganymede	Long	Low
Titan	Long	Low
Moon	Long	High and low
	Short	Low

Fig. 1 Long wavelength, low resolution spectrum of Mars recorded on April 1978 with a small aperture. The system response function has not been removed. Exposure time is 15 s.

this configuration the northern hemisphere contributed ~60–65% of the total reflected light. The water vapour content of the Mars lower atmosphere becomes considerable during the late spring and its subsequent photodissociation leads to a process which inhibits ozone formation^{3–7}. Mariner 9 observed about 10 μ atm of ozone near the north pole of Mars at the equivalent seasonal time in 1972 (ref. 6), but detected no ozone near the equatorial region. Because the aperture was locked onto the centroid of light at least $1\frac{1}{2}$ arc s of the north polar region of Mars was excluded from the spectrometer. It is highly unlikely that ozone would have extended southwards from the north polar region to latitudes as far south as $+45^\circ$. Thus, if the seasonal characteristics in 1978 were similar to those in 1972, virtually no ozone should have been in the martian atmosphere which was included in the aperture. Confirming studies of the ozone seasonal characteristics will have to wait until about December 1978 when the winter–spring transition can be observed in the southern hemisphere and when one should expect to detect atmospheric ozone.

Acquiring data from the jovian system requires special considerations and techniques. Figure 3 displays the reflected light spectrum of Io (J1), Jupiter's innermost galilean satellite. The region near 2,900 Å is slightly saturated and fiducial marks on the camera faceplate account for the two apparent absorption features near 2,580 and 3,305 Å. An observation time was chosen when Io and Ganymede were simultaneously near elongation, as seen from Earth, and had minimal differential motions for several hours. The tracking procedure required FES acquisition of Jupiter, which is much too large and too bright to be useable for the tracker, followed by FES lock-up on Ganymede. The spacecraft gyros were trimmed to the Ganymede celestial motion and Io was subsequently manoeuvred into the large slot. The FES continued to lock on Ganymede while the 10 min exposure was in progress. Direct tracking on Io with the 'spill-over' light surrounding the large or small aperture (the

Fig. 2 Ratio of the spectrum of Mars (Fig. 1) to that of the Moon. Both spectra were recorded with IUE and the ratio was constructed from data which had received identical processing. The flux ratio is in arbitrary, linear units. No ozone absorption band is observed at 2,550 Å.

method used for Mars) is generally not possible because the scattered light from Jupiter is about equal to the 'spill-over' light from Io at Io's position in the tracker field. Europa (J2) may also have to be handled by this differential guiding technique, but Ganymede and Callisto are sufficiently removed from the visible scattered light domain of Jupiter to be directly tracked most of the time. Whenever any satellite is too close to Jupiter, within ~7 jovian radii, differential tracking will be necessary. This condition will also be true for satellite studies of the saturnian system. The spectrum of Io has not undergone extensive analysis because the data were acquired during a high radiation background portion of the IUE orbit and more background noise removal is necessary before proceeding further. Nonetheless, acquisition of Io's spectrum certainly demonstrates one of the capabilities of IUE.

Fig. 3 Long wavelength, low resolution spectrum of Io using a large slot. The system response function has not been removed. Exposure time is 10 min.

The observation of Solar System objects with IUE is more complicated than that required for the classes of stars and galaxies for which IUE was originally designed. The significant differences are: (1) the range of visual magnitude brightness is very large, from -4 for Venus to fainter than +11 for some satellites of Saturn. This complicates acquisition and tracking. (2) Most of the bodies in the Solar System move at non-sidereal rates. Special tracking procedures need to be developed to acquire spectra of planetary satellites, regions of the bright disks of Jupiter, Saturn, Mars, Venus and the Moon. (3) All of the objects in this class echo the time variable solar spectrum, to first order. To examine the spectral range from 1,150 to 3,200 Å requires numerous exposures to cover a 10^5 brightness range with a detector system which is linear over about a ratio of 25 in object brightness in the UV. (4) Perhaps the most pressing complication facing IUE planetary observers is the acquisition of comparison solar spectra. Ideally they should be acquired by IUE itself so that all of the instrumental parameters are removed. IUE cannot look directly at the Sun, but the fully illuminated disk of the Moon near zero phase angle seems to be the best current choice for monitoring the solar spectrum. Some minor tracking difficulties still remain for accomplishing this, but they seem to be solvable. Alternate G type stars are being examined as another possibility to tie together solar spectral references.

All of these difficulties are temporary and excellent progress is being made to develop a powerful, useable system for the study of the Solar System in the UV. A brief inspection of the data acquired so far confirms that IUE is capable of providing measurements which can supply crucial answers to several of the more significant problems in planetary science.

Nucleosomes are assembled by an acidic protein which binds histones and transfers them to DNA

R. A. Laskey, B. M. Honda, A. D. Mills, & J. T. Finch

MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

The nucleosome subunits of chromatin are assembled from histones and DNA by an acidic protein which binds histones. The nucleosome assembly protein has been identified and purified from eggs of Xenopus laevis.

DNA in eukaryotic chromosomes is packed into a repeating chain of nucleosome subunits, each consisting of an octamer of histones complexed to approximately 200 base pairs of DNA (for reviews see refs 1 and 2). This article describes the identification and purification of a protein which binds histones and transfers them to DNA to form nucleosomes. The nucleosome assembly protein has been purified from unfertilised eggs of the frog *Xenopus laevis* by fractionating a cell-free nucleosome assembly system³. The cell-free system converts purified DNA into a regularly repeating chain of nucleosomes at a rate of 5×10^7 nucleosomes per s per egg³ using either the egg's endogenous histone pool⁴⁻⁶ or exogenous sources of purified histones. Assembly is not dependent on DNA synthesis³. The products obtained when DNA is incubated in the cell-free system were recognised as chains of nucleosomes by the criteria of: (1) sedimentation, (2) buoyant density, (3) beaded appearance in the electron microscope, (4) localised resistance to micrococcal nuclease, (5) histone dependence and (6) insertion of superhelical turns into relaxed circular DNA^{3,7}. We have used histone dependent insertion of superhelical turns into relaxed circular DNA as a rapid assay for nucleosome assembly because Germond *et al.*⁸ have shown that the number of superhelical turns is directly related to the number of nucleosomes on the DNA. This supercoiling activity should not be confused with the DNA gyrase of prokaryotes which also inserts superhelical turns into DNA⁹. In contrast to the activity we describe here, DNA gyrase requires ATP but does not require stoichiometric amounts of structural proteins such as histones, and in addition its activity is counteracted by nicking closing enzyme⁹.

An assembly factor is required for ordered interaction of histones with DNA

Nucleosomes can be reconstituted from separated DNA and histones by prolonged dialysis from $>1\text{M NaCl} \pm 5\text{M urea}$ (reviewed in ref. 2), but at physiological ionic strength mixtures of DNA and histones precipitate. Addition of small amounts of *Xenopus* egg homogenate prevents precipitation and results in nucleosome formation^{3,7}, suggesting that eggs contain an additional factor which is required for the ordered interaction of histones with DNA to form nucleosomes at physiological ionic strength.

The nucleosome assembly factor is a protein

To determine the nature of the assembly factor in eggs of *Xenopus laevis*, egg homogenates were incubated with a variety of specific degradative enzymes before assaying for assembly activity. The results are summarised in Table 1. The assembly factor is unlikely to contain a nucleic acid component since it is totally resistant to ribonuclease A, and micrococcal nuclease.

The assembly factor is also resistant to trypsin and chymotrypsin, but assembly is only observed if the proteases are inhibited by phenylmethylsulphonyl fluoride (PMSF) after digestion and if exogenous histones are added. (Exogenous nicking-closing enzyme is also required after digestion in order to visualise assembly by monitoring insertion of superhelical

Table 1 Sensitivity of the assembly factor to degradative enzymes

Enzyme preincubated with egg supernatant	Enzyme inhibitor	Assembly activity (using added histones)
Ribonuclease A ($500\text{ }\mu\text{g ml}^{-1}$)	Nil	+
Micrococcal nuclease ($1,500\text{ units ml}^{-1}$) + 2 mM CaCl_2	EDTA (5mM)	+
Trypsin ($250\text{ }\mu\text{g ml}^{-1}$)	PMSF†	+
Chymotrypsin ($<1\text{ mg ml}^{-1}$)	PMSF†	+
Proteinase K ($250\text{ }\mu\text{g ml}^{-1}$)	PMSF†	—
PMSF + proteinase K ($250\text{ }\mu\text{g ml}^{-1}$)	Inhibited before incubation	+

Xenopus egg homogenates were prepared and clarified as described previously³ except that 0.66 volumes of 120 mM KCl , 2 mM MgCl_2 , $20\text{ mM Tris-HCl pH } 7.5$ were added after homogenisation and the $1,800\text{ g}$ supernatant was centrifuged twice at $145,000\text{ g (max)}$ for 30 min. $20\text{ }\mu\text{l}$ of clarified homogenate was incubated with each enzyme for 1 h at 25°C . Enzymes were then inhibited before addition of $1\text{ }\mu\text{g calf thymus histones}$, $0.5\text{ }\mu\text{g SV40 form I relaxed DNA}$ and nicking-closing enzyme which had been partially purified from eggs of *X. laevis* by chromatography on DEAE-cellulose and phosphocellulose columns¹². Assembly was assayed by incubation at 20°C for 3 h followed by agarose gel electrophoresis to reveal superhelical turns¹³. PMSF was dissolved in ethanol at 6 mg ml^{-1} and added to homogenates to give a final concentration of $150\text{ }\mu\text{g ml}^{-1}$.

* When micrococcal nuclease was not inhibited following pre-incubation, the SV40 DNA was completely degraded.

† When PMSF was omitted ^{35}S -labelled histones added to the incubation were digested to complete solubility in 5% trichloroacetic acid containing 0.25% sodium tungstate.

turns into relaxed DNA.) The resistance to trypsin and chymotrypsin suggests either that the assembly factor is not a protein or that it is a protein which lacks exposed basic and aromatic amino acids on its surface. To distinguish these two possibilities we tested its sensitivity to proteinase K (BDH, twice crystallised), a single protease which cleaves most types of accessible peptide bond and which is completely and irreversibly inhibited by PMSF¹⁰. The assembly activity is abolished by incubation with proteinase K. The destruction of activity is more rapid and more complete when the preincubation is performed above pH 8. Addition of histones with or without nicking-closing enzyme fails to restore any activity. When the proteolytic activity of proteinase K preparations is inactivated by PMSF before incubation with egg homogenates the assembly activity remains undiminished (Table 1), confirming that the loss of activity caused by proteinase K is due to proteolysis.

Identification and purification of a protein which co-purifies with assembly activity

To identify any proteins which co-purify with the assembly activity, clarified egg homogenates (see Table 1 legend) were initially fractionated by sedimentation through a 10–40% sucrose gradient. The distribution of polypeptides in the gradient fractions was examined by polyacrylamide gel electrophoresis of aliquots (Fig. 1a). Simultaneously each fraction was assayed for its ability to insert superhelical turns into SV40 circular DNA which had been relaxed by nicking-closing enzyme as described previously³. The number of superhelical turns is related to the number of nucleosomes on the DNA⁸. Figure 1b demonstrates that a sharp peak of activity is observed. The sedimentation rate of the most active fraction was previously estimated as "approximately 11S"⁷. Centrifugation for longer times in a rotor which generates greater force (SW 60Ti) collection and assay of a larger number of fractions and comparison with a wider range of markers (catalase, glyceraldehyde-3-phosphate dehydrogenase and alkaline phosphatase) reveals that this is an overestimate and that the value is nearer to 8S. Figure 1a shows that the active fractions contain a wide range of polypeptides, but that many others are removed by this simple fractionation.

When crude undiluted homogenates are heated to 80 °C for 10 min a gelatinous precipitate forms and assembly activity is lost, hence we described the activity as thermolabile³. However, when the active fractions from a sucrose gradient (or diluted, twice reclarified homogenates) are heated 10 min at 80 °C the supercoiling activity is not precipitated; it is simply made dependent on added histones and nicking-closing enzyme. Figure 1c shows that heating 10 min at 80 °C followed by cooling and centrifuging 2 min at 10,000g to remove precipitated proteins causes a dramatic simplification of the polypeptide profile. One major polypeptide (arrow in Fig. 1c) remains. It has an apparent molecular weight of 29,000, judged by comparison with known standards on SDS-gel electrophoresis (superoxide dismutase, 20,000; aldolase, 30,000; glyceraldehyde-3-phosphate dehydrogenase, 36,000; creatine kinase, 40,000; ovalbumin, 43,000). It migrates slightly slower than histone H1 (which migrates as though it has an apparent molecular weight of 27,500 in the electrophoresis conditions used here). The polypeptide of MW 29,000 is not visible in the unheated sample (Fig. 1a). It is obscured by a more prominent band which migrates just ahead of it (which is not histone H1). Note that the distribution of the polypeptide marked by an arrow in Fig. 1c is similar to the distribution of assembly activity in Fig. 1b. Most of the minor bands in the fraction marked by an arrow can be removed from the heated gradient fraction by a second centrifugation at 10,000g for 2 min. To obtain optimal precipitation of other proteins it is necessary to add 0.025 volumes of 6 mg ml⁻¹ PMSF in ethanol before heating. Ethanol alone substitutes partially but not completely.

Figure 2 shows that assembly activity also co-purifies with a polypeptide which has an apparent molecular weight of 29,000

Fig. 1 Nucleosome assembly activity co-sediments with a particular protein in a sucrose gradient. *a*, SDS gel of proteins; *b*, DNA supercoiling assay; *c*, SDS gel of proteins as (*a*) which resist heat precipitation. Details are as follows: *a*, Separation of polypeptides contained in each sucrose gradient fraction by electrophoresis in a 15% polyacrylamide gel as described previously¹⁴, and visualised by Coomassie blue staining. *b*, Assay of each gradient fraction for insertion of superhelical turns into relaxed circular ³H-SV40 DNA. DNA configurations are resolved by electrophoresis through a 1% agarose gel and visualised by fluorography using 3% PPO in ethanol⁵. 0.1 µg of ³H-SV40 relaxed DNA was incubated in 50 µl of each gradient fraction for 3 h at 20 °C. *c*, Same as (*a*) but gradient fractions were heated 10 min at 80 °C (after addition of 0.025 volumes 6 mg ml⁻¹ PMSF in ethanol), cooled at 0 °C for 5 min, centrifuged 2 min 10,000g, at 4 °C to remove precipitated proteins and only the supernatant was treated with SDS for electrophoresis. Before gradient centrifugation 500 µl clarified egg homogenate was extracted twice with an equal volume of 1,1,2-trichlorotrifluoroethane to remove lipids and lipoproteins (such as yolk), then diluted with 100 µl of 20 ml tris pH 7.5, 5 mM EDTA. It was centrifuged through a 10–40% sucrose gradient⁷ for 16.5 h at 38,000 r.p.m. in a Beckman SW 40Ti rotor at 4 °C. Aliquots of 50 µl were prepared for electrophoresis (*a* and *c*) and assayed for assembly (*b*).

Fig. 2 Nucleosome assembly activity co-elutes with a polypeptide of MW 29,000 during anion exchange chromatography on DEAE-cellulose. *a*, Assay of each DEAE-cellulose column fraction (15 μ l diluted to 50 μ l at final KCl concentration of 120 mM) for insertion of superhelical turns into relaxed SV40 circular DNA (0.25 μ g) in the presence of calf thymus histones (0.5 μ g) and nicking-closing enzyme (see Table 1 legend). Products of a 3 h incubation at 20 °C were analysed by agarose gel electrophoresis and ethidium bromide staining. A negative image is shown to facilitate half-tone reproduction. *b*, Electrophoretic analysis of polypeptides contained in each column fraction on a 15% polyacrylamide SDS gel in conditions of Fig. 1*a* and *c*. The marker track M is the material from the track marked with an arrow in Fig. 1*c*, re-electrophoresed on this gel (that is, a heated sucrose gradient fraction). 6 ml of clarified egg homogenate was chromatographed on a 9 $\times$ 3 cm DEAE-cellulose (Whatman DE 52) column and eluted with a 150 ml linear KCl gradient from 0.12 M to 0.5 M KCl in 20 mM Tris-HCl pH 7.5. 12- μ l aliquots were diluted to 52 μ l at a final concentration of 120 mM NaCl for assay. Fractions eluting after 350 mM KCl are not shown. They contained very few proteins and showed no activity.

when clarified homogenates are fractionated by charge. Thus both the polypeptide and the activity bind tightly to the anion exchanger DEAE-cellulose suggesting that the assembly factor is highly negatively charged. After chromatography on DEAE-cellulose the assembly factor requires the addition of histones and nicking-closing enzyme in order to insert superhelical turns into relaxed DNA. When the protein of MW 29,000 is purified by heating sucrose gradient fractions and then chromatographed on DEAE-cellulose it again co-elutes with the assembly activity.

Therefore the activity which inserts superhelical turns into relaxed DNA co-purifies by both size and charge with a protein whose subunits have an apparent MW of 29,000 on SDS gels.

Figure 3*a* demonstrates the electrophoretic purity of the polypeptide prepared by sucrose gradient centrifugation followed first by heating for 10 min at 80 °C as in Fig. 1*c* and then by chromatography on DEAE-cellulose (as in Fig. 2).

Figure 3*b-d* shows that the preparation containing the purified protein illustrated in Fig. 3*a* causes the insertion of superhelical turns into relaxed DNA in the presence of acid extracted histones and nicking-closing enzyme. In the absence of the material shown in Fig. 3*a* or of the histones, assembly does not occur (Fig. 3*b-d*). Most nucleic acid contaminants are removed from the polypeptide of MW 29,000 by DEAE chromatography, but to ensure that nucleic acids or oligonucleotides are not required for its activity, a separate preparation of the protein (prepared without the final DEAE step) was incubated with 100 μ g ml⁻¹ ribonuclease A and 150 units ml⁻¹ micrococcal nuclease (in 2 mM CaCl₂) for 2 h at 25 °C followed by chromatography on Sephadex G-75 to remove oligonucleotides, CaCl₂ and the nucleases. Figure 3*e-g* illustrates that assembly activity is not decreased by this procedure.

All preparations which have demonstrated assembly activity have also contained the polypeptide of 29,000 MW. The sedimentation and gel filtration properties of the native form of this polypeptide suggest that the native protein is unlikely to consist of less than four subunits of MW 29,000.

Fig. 3 The purified protein of 29,000-dalton subunits inserts superhelical turns into relaxed DNA in the presence of histones and nicking-closing enzyme. *a*, Electrophoretic purity of the polypeptide of MW 29,000 prepared by sucrose gradient centrifugation (as in Fig. 1) followed first by heating 10 min 80 °C (as in Fig. 1*c*) and then by chromatography on DEAE-cellulose (as in Fig. 2). The figure shows a microdensitometer trace of a stained 15% SDS-polyacrylamide gel. *b-d*, Assay of the material from (*a*) for insertion of superhelical turns into relaxed DNA (as in Fig. 2*a*); *b*, in the presence of histones (extracted from mouse fibroblasts by 0.2 M H₂SO₄) and nicking-closing enzyme (purified as in legend to Table 1); *c*, as *b*, but histones omitted; *d*, as *b* but the purified nucleosome assembly protein (illustrated in Fig. 3*a*) was omitted. *e-g*, as *b-d* but using assembly protein (not shown) which had been prepared by incubating a heated sucrose gradient fraction with 100 μ g ml⁻¹ ribonuclease A and 150 unit ml⁻¹ micrococcal nuclease (in 2 mM CaCl₂, 50 mM NaCl, 10 mM Tris pH 8.0) for 2 h at 25 °C followed by chromatography on Sephadex G-75 (in 0.5 mM EDTA, 50 mM NaCl, 10 mM Tris pH 7.5) to remove oligonucleotides and the nucleases.

Figure 4 illustrates two other criteria which indicate that the protein described assembles nucleosomes. The sedimentation profile of the incubation product resembles that of naturally-occurring SV40 nucleohistone complex and contains approximately equal amounts of histones and DNA (Fig. 4*a*). In addition the incubation product has the characteristic beaded appearance of the SV40 minichromosome (Fig. 4*b*).

Nicking-closing enzyme is not required for nucleosome assembly. Although it is required to relax torsion so that the insertion of superhelical turns into DNA can be visualised in the gel assay, it is not required when nucleosome assembly is

Fig. 4 The protein of 29,000-dalton subunits causes DNA and histones to form a discrete nucleoprotein complex.

a. Velocity sedimentation of the nucleoprotein product obtained by incubating $0.1 \mu\text{g}$ ^3H -SV40 form I ($55,000 \text{ c.p.m. } \mu\text{g}^{-1}$) DNA (●) with $0.2 \mu\text{g}$ ^{35}S -labelled mouse fibroblast histones ($7,000 \text{ c.p.m. } \mu\text{g}^{-1}$) (○), in the presence of $20 \mu\text{l}$ of the heated peak fraction from a sucrose gradient (similar to the track marked by an arrow in Fig. 1c). After incubation for 3 h at 20°C without nicking-closing enzyme the product was centrifuged through a 10–30% sucrose gradient in 60 mM KCl, 1 mM EDTA, 10 mM Tris pH 7.5 for 70 min at 50,000 r.p.m. in a Beckman SW60Ti rotor. The arrow marked 'DNA' indicates the position of free SV40 DNA form I and the arrow marked 'DNP' indicates the position of authentic SV40 minichromosome from infected cells. **b.** Electron micrographs of the nucleoprotein product obtained by incubation in the conditions described in **a** followed by spreading and shadowing as described previously⁷. (Nicking-closing enzyme was included in the incubations illustrated in **b**, but it is not necessary for the formation of such structures.) $\times 130,000$.

monitored by sedimentation or electron microscopy. For these assay methods the purified assembly protein (as illustrated in Fig. 3a) is sufficient to convert histones and DNA into nucleosomes.

The protein which co-purifies with assembly activity binds histones to form an active complex

Figure 5 illustrates that the purified nucleosome assembly protein binds labelled histones. All four of the nucleosome core histones bind and co-sediment as a complex with the assembly protein (at approximately 8S). The complex sediments much faster than free histones and slightly, but reproducibly, faster than the free assembly protein. Coomassie blue staining of gels followed by microdensitometry and comparison with standard histone preparations from nuclei reveals that all four of the nucleosome core histones are present in the complex in approximately equimolar amounts. Histone H-1 has not been detected so far but this could be due to technical causes.

The formation of the complex between histones and the nucleosome assembly protein is unlikely to be a nonspecific, electrostatic adsorption artefact for several reasons. First, at low histone concentrations essentially all of the histones sediment as a uniform, discrete complex. Second, when the histone concentration is increased binding can be saturated without causing the complex to aggregate or sediment faster; instead the excess histones sediment as free histones. Third, the assembly protein masks sufficient positive charges on the histones to inhibit their binding to CM-cellulose at neutral pH. Fourth, if small amounts of labelled histones are added to crude egg homogenates the added histones sediment discretely as the complex described here, indicating that the vast excess of cellular proteins does not compete effectively for histone binding against the nucleosome assembly protein, even though several of the other cellular proteins are more acidic than the assembly protein. Fifth, when the complex formed between the purified assembly protein and labelled histones is isolated from a sucrose gradient and incubated with DNA the histones are transferred to the DNA with the formation of a beaded nucleoprotein complex which contains supercoiled DNA.

Cross-linking studies should provide further information on the specificity and stoichiometry of histone binding.

Properties of the nucleosome assembly protein

The protein which co-purifies with nucleosome assembly activity electrophoreses as a rather broad band with an apparent MW of 29,000 in SDS-polyacrylamide gels. When it is electrophoresed over long distances it resolves into two distinct bands, suggesting that the band seen in Figs 1–3 probably

contains more than one polypeptide chain. Its sedimentation and gel filtration properties suggest that the native protein is larger than 100,000 daltons. It does not bind to CM-cellulose above pH 6 but binds to DEAE-cellulose and elutes between 0.3 M and 0.4 M KCl at pH 7.5, suggesting that it is strongly

Fig. 5 The nucleosome assembly protein binds histones. **a.** distribution of ^{35}S -methionine labelled, acid-extracted mouse histones after centrifugation through a 10–30% sucrose gradient. ●, Histones were incubated with a $10\times$ concentrated (Minicon B-15) heated sucrose gradient fraction (as marked by arrow in Fig. 1c) with 50 mM NaCl for 20 min before centrifugation in a separate tube from the free histone marker (○). Radioactivity was measured by liquid scintillation counting 50- μl aliquots of each fraction in Aquasol. Fractions from (a) (●) were pooled in pairs and 50- μl aliquots were electrophoresed in a 15% polyacrylamide gel (as in Fig. 1a) to locate the polypeptide of MW 29,000 by Coomassie blue staining. (At the histone concentration used in this figure histone bands were stained too faintly for photographic reproduction.) The bracket marked N indicates the position of the nucleosome assembly protein when it is centrifuged in the absence of histones (fractions 9 and 10). Centrifugation was for 20.5 h at 50,000 r.p.m. in a Beckman SW60Ti rotor at 4°C . Gradients contained in 2mM EDTA, 20mM Tris-HCl pH 7.5.

acidic. This conclusion is confirmed by isoelectric focusing. Thus on two dimensional gels¹¹ the protein has an isoelectric point of 5.

Additional evidence that this protein is indeed responsible for nucleosome assembly comes from the observation that it shows the same remarkable resistance to thermal denaturation and proteolytic degradation as the assembly activity. Thus its sedimentation as a multi-subunit structure and its ability to bind histones are not affected by heating. After prolonged treatment with chymotrypsin the protein's sedimentation constant is only slightly decreased and it continues to bind histones. Electrophoresis reveals that at least one cut has occurred in each polypeptide chain, since the band of MW 29,000 is replaced by two large fragments of MW approximately 26,000 but which still sediment as a multi-subunit structure. Proteinase K at pH 10 which abolishes the assembly activity also cleaves the protein, generating fragments of less than 20,000 daltons.

Five ml of egg homogenate (3 ml packed eggs + 2 ml buffer) containing 1.25 g total protein yields 160 µg of pure protein. 1 µg of pure protein can convert at least 0.25 µg DNA into nucleosomes in the presence of 0.5 µg histones.

The nucleosome assembly process

When histones and DNA are mixed in solution at physiological ionic strength, they instantly form a precipitate. When the protein described here is mixed with histones before addition of DNA, precipitation is prevented and nucleosomes form. We observed previously that the egg's histone pool is complexed to a large negatively charged molecule and that fractions containing this complex interact with DNA to form nucleosomes⁷. Therefore we proposed that histones are organised into nucleosome precursor complexes by an acidic factor which has a 'catalytic' role in the assembly process⁷. The protein we have purified clearly binds histones and transfers them to DNA to form nucleosomes. The possibility that it is recycled remains to be tested.

Nucleosomes can be assembled by prolonged dialysis from 2 M NaCl (reviewed in ref. 2). Therefore it seems that the spatial information required for histone-histone interactions and histone-DNA interactions resides in the histones and DNA themselves. We suggest that the role of the protein we have purified is that of a 'molecular chaperone' which prevents incorrect ionic interactions between histones and DNA. Thus by binding histones and neutralising their positive charges the

nucleosome assembly protein could prevent nonspecific ionic interactions and allow only selected specific interactions to occur. The additional possibility that specific interactions between different histones occur in the complex formed with the nucleosome assembly protein remains to be tested.

The nucleosome assembly reaction studied here seems to have very simple requirements. It requires only the protein preparation illustrated in Fig. 3a, DNA and acid extracted (or salt extracted) histones incubated in NaCl (or KCl) concentrations between 50 mM and 150 mM. It is inhibited by higher NaCl concentrations. The reaction will proceed to completion in 3 h at 0°C. We have been unable to find requirements for low molecular weight co-factors, such as Mg²⁺ or ATP.

Eggs of *Xenopus laevis* are unusual in that they divide to form 5,000 cells in 5 h with some cell cycles of only 10 min. In addition they accumulate a large histone pool, sufficient for 15,000 nuclei⁴⁻⁶. Therefore it is possible that the nucleosome assembly protein we have described is only an adaptation to this rapid rate of chromosomal replication. However, during the course of this work we have found that mouse fibroblast nuclei and wheat embryos also contain a thermostable protein which converts histones and DNA into nucleosomes (B.M.H., A.D.M. & R.A.L., in preparation). Therefore it will be interesting to determine if the protein we have described is a universal mechanism for assembling the nucleosome subunits of eukaryotic chromatin.

We thank John Gurdon, Aaron Klug and Doug Melton for comments on the manuscript, and Geoff Partington for suggesting extraction with trichlorofluoroethane. B.M.H. is a post-doctoral fellow of the Canadian MRC.

Promoter-specific inhibition of transcription by antibiotics which act on DNA gyrase

C. L. Smith*

The Public Health Research Institute of The City of New York, Inc., 455 First Avenue, New York, New York 10016

M. Kubo & F. Imamoto

Research Institute for Microbial Diseases, Osaka University, Yamada-Kami, Suita, Osaka, Japan

Nalidixic acid, novobiocin and coumermycin specifically inhibit phage promoter-dependent transcription of the trp operon in ϕ 80ptp but not transcription from the authentic trp promoter. The nalidixic acid inhibition is not observed in an E. coli strain containing a nalA^r mutation. These results indicate that DNA gyrase is involved in transcription.

* Present address: Department of Biological Sciences, Columbia University, New York, New York 10027.

DNA GYRASE catalyses the ATP dependent introduction of negative superhelical twists into double stranded closed circular DNA in *Escherichia coli*¹. This activity is required for λ integrative recombination² and replication of *E. coli*^{3,4}, plasmids^{5,6} and bacteriophages⁷⁻⁹. DNA gyrase is inhibited by the antibiotics coumermycin and novobiocin¹⁰. The *cou* locus mapping close to the *dnaA* at 82 min on the *E. coli* map determines resistance to these drugs^{11,12}.

DNA gyrase activity is also inhibited by nalidixic acid (NAL) and oxolinic acid^{13,14}. Resistance to these drugs is determined by

the *nalA* locus mapping at 48 min on the *E. coli* map¹⁵. It is thought that the nick closing activity required in the supercoiling reaction resides in the NAL target protein, *pnaI*, because (1) the ATP independent DNA gyrase catalysed relaxation of supercoiled DNA is inhibited by NAL and oxolinic acid but not by novobiocin or coumermycin and (2) incubation of DNA gyrase and DNA with NAL or oxolinic acid results in the formation of a relaxation type complex.

At low doses NAL is thought to be a specific inhibitor of DNA replication in *E. coli*. However at higher doses several workers have observed inhibition of transcription¹⁶⁻¹⁸. In preliminary experiments we observed indications that NAL interfered with $\phi 80$ phages transcription at doses normally thought to inhibit only DNA replication. Here we report the effect of NAL on transcription of the tryptophan (*trp*) operon integrated into the $\phi 80$ phage genome.

Nalidixic acid is a promoter-specific inhibitor of *trp* expression

When the bacterial *trp* operon is integrated into the λ phage genome, transcription of the operon may initiate at either the authentic *trp* promoter (P_{trp}) or at the leftward phage promoter as shown in Fig. 1^{19,20}. Initiation of transcription from P_{trp} is turned off in the presence of tryptophan and the *trp* repressor. Read-through transcription of the *trp* operon from the leftward phage promoter can occur in the presence of the *trp* repressor but is completely inhibited when phage repressor molecules are present. Subsequent studies yielded identical results with $\phi 80ptrp$ phages^{21,22}.

Infection of a nonlysogenic *E. coli trpE*⁻ strain (MO1512) with bacteriophage $\phi 80ptrp$, in the presence of tryptophan, led to immediate synthesis of anthranilate synthetase (ASase; product of the *trpED* genes) as shown in Fig. 2a. ASase synthesis occurred by the read-through transcription of the *trp* operon since no phage repressor molecules were present in the host cell. However, when the $\phi 80ptrp$ infected cells were incubated in the presence of 40 $\mu\text{g ml}^{-1}$ NAL, no ASase activity was detected even after prolonged incubation.

The effect of NAL on ASase synthesis originating at the P_{trp} promoter is shown in Fig. 2b. In this experiment *E. coli* strain MO1513 *trpE*⁻ ($\phi 80^+$) was infected with $\phi 80ptrp$ in the absence of tryptophan. ASase synthesis, due to transcription from the authentic *trp* promoter, began immediately after removal of tryptophan from the culture medium, as shown by the control cells in Fig. 2b. When NAL was present only a slight decrease in ASase activity was seen throughout the incubation period. Dose-response curves for a 60-min incubation are shown in Fig. 3a. Concentrations of NAL which virtually eliminate ASase synthesis originating from the phage promoter have essentially no effect on synthesis originating from P_{trp} .

Nalidixic acid inhibition occurs in the absence of DNA replication

The amount of ASase synthesised in the procedure used in Figs 2 and 3 is regulated by the number of $\phi 80ptrp$ templates available for transcription²². Thus, it was possible that NAL inhibited ASase synthesis simply by interfering with phage replication. Therefore, the effect of NAL on phage promoter dependent ASase synthesis was examined in the absence of DNA replication. An *E. coli* strain lacking DNA polymerase I and II and containing a temperature-sensitive DNA polymerase III (*polA*⁻, *polB*⁻, *polC*_{ts}) was infected with $\phi 80ptrp$ and treated with NAL. As shown in Fig. 4a, addition of NAL to $\phi 80ptrp$ infected cells incubated at 30°C led to rapid partial inhibition of ASase synthesis by the read-through mechanism. Addition of NAL to $\phi 80ptrp$ -infected cells incubated at the restrictive temperature also led to inhibition of phage promoter controlled ASase synthesis (Fig. 4b). However, somewhat less inhibition was observed at the restrictive temperature than at the permis-

Fig. 1 Transcriptional map of bacteriophages $\phi 80$ and λ carrying the *E. coli trp* operon. P_T , authentic *trp* promoter (repressed by tryptophan but not by phage repressor); P_L , early leftward phage promoter (repressed by the phage repressor but not by tryptophan).

sive temperature. This indicates a small portion of the NAL inhibition may arise from interference with replication but most of the effect is replication independent.

Nalidixic acid inhibits phage promoter-directed *trp* transcription

DNA-RNA hybridisation experiments were conducted to determine whether NAL inhibition was occurring at the level of transcription or translation. The results of these experiments are summarised in Table 1. Addition of NAL to $\phi 80ptrp$ infected cells reduced the amount of phage promoter-controlled *trp* mRNA synthesis to about 10% of the level observed in the absence of the drug. On the other hand, the drug caused a slight increase in the amount of mRNA derived from the P_{trp} promoter. The effects observed with chloramphenicol are very different. Chloramphenicol specifically inhibits P_{trp} transcription but does not affect phage transcription. Similar chloramphenicol effects have been observed in $\lambda ptrp$ phages^{23,24}.

We considered the possibility that NAL was stimulating degradation of the phage promoter initiated mRNA rather than inhibiting mRNA synthesis. The effect of NAL on the stability of preformed mRNA is shown in Fig. 5. In these experiments rifampicin was added at the time of addition of NAL to inhibit mRNA initiation. NAL did not significantly increase the rate of *trp* mRNA degradation.

At low concentrations NAL inhibits DNA replication^{18,25,26}. At these concentrations transcription is not inhibited as judged both by incorporation of labelled precursor into RNA^{18,25,26} and by direct examination of several bacterial operons¹⁷. Based on

Fig. 2 Nalidixic acid inhibition of ASase synthesis directed by a $\phi 80ptrp$ template. (a) Read-through transcription from the phage promoter in a *nalA*⁺ strain. In the presence of tryptophan, strain MO1512 *trpE*⁻ was grown to a density of 2×10^8 cells ml^{-1} , infected with $\phi 80ptrp$ and treated with 40 $\mu\text{g ml}^{-1}$ NAL (●). (b) Transcription from the authentic *trp* promoter in a *nalA*⁺ strain. In the absence of tryptophan, strain MO1513 *trpE*⁻ ($\phi 80$) was grown to a density of 2×10^8 cells ml^{-1} and in the absence of tryptophan, infected with $\phi 80ptrp$ and treated with 40 $\mu\text{g ml}^{-1}$ NAL (●). (c) Read-through transcription from the phage promoter in a *nalA*⁻ strain. In the presence of tryptophan, strain MO15124 *trpE*⁻ *nalA26* was grown to a density of 2×10^8 cells ml^{-1} , infected with $\phi 80ptrp$ and treated with 40 $\mu\text{g ml}^{-1}$ NAL (●). Controls: in all cases were—infected with $\phi 80ptrp$ but not treated with NAL (○—○); not infected with $\phi 80ptrp$ and not treated with NAL (○—○). Experimental procedures are described in full elsewhere²³.

Fig. 3 Inhibition of ASase synthesis by various concentrations of nalidixic acid (a), novobiocin (b) and coumermycin (c). The per cent activity was calculated from the amount of ASase activity observed at 60 min at the indicated dose. 100% activity was 39 units ml⁻¹ for phage directed synthesis (●) and 6.7 units ml⁻¹ for P_{trp} directed synthesis (○). Experimental procedures are described in Fig. 2.

these results it has been assumed that NAL is a specific inhibitor of DNA replication. However, our results show that transcription monitored by the production of competent mRNA and also by enzyme synthesis can be inhibited by the same NAL doses previously believed only to inhibit DNA replication. Therefore, NAL should not be used as a specific inhibitor of DNA replication.

In 1973, Puga and Tessman¹⁶ reported that nalidixic acid interfered with plasmid phage S13 mRNA synthesis at drug levels which did not affect host mRNA synthesis. Since all S13 mRNA synthesis was equally inhibited and it had been previously observed that intercalating dyes inhibited transcription²⁷, these authors proposed that the specificity of the inhibition was due to a preferential intercalation of the antibiotic into the supercoiled plasmid DNA. However, our results show that NAL inhibits, with total specificity, one of the two promoters both of which serve the same operon and are on the same

Fig. 4 Nalidixic acid inhibition of phage promoter dependent ASase synthesis in the presence (30 °C) and absence (42 °C) of DNA replication. Strain BT10266 *polA*⁻, *polB*⁻, *polC*_{ts} was grown to 2 × 10⁸ cells ml⁻¹ by incubation at 30 °C in minimal medium containing tryptophan²³. Following infection with ϕ80_{trp} the culture was divided into two portions, one of which was further incubated in fresh minimal medium at 30 °C while the other was incubated at 42 °C. After 15 min, 40 μg ml⁻¹ NAL was added to portions of each of the cultures and the incubation at the respective temperature continued (●—●). Controls: infected with ϕ80_{trp} but not treated with NAL (○—○); not infected with ϕ80_{trp} and not treated with NAL (○—○—○).

plasmid molecule. Therefore, the simple notion that superhelical density generates NAL specificity must be rejected.

In experiments shown in Fig. 4 only partial inhibition of phage promoter controlled ASase synthesis was observed. This is in contrast to the complete inhibition observed in the experiment shown in Fig. 2. In the former experiment NAL was added after initiation of transcription whereas in the latter experiment it was added just before. However, the former experiment also involved a multiple mutant strain while the latter involved a wild-type strain. To determine which of these factors was significant NAL was added to the same wild-type strain used for Fig. 2 but after transcription was initiated. A partial inhibition of ASase synthesis was seen just like that shown in Fig. 4 (data not shown). As the effect of NAL is greater when added before transcription initiates, it is likely that NAL acts preferentially on initiation.

DNA gyrase is involved in transcription

Mutations at the *nalA* locus confer NAL resistance to DNA synthesis^{18,27}. To see if this same locus was involved in NAL sensitive transcription we examined ASase synthesis in a derivative of *E. coli* strain MO1512 containing the *nalA26* mutation (Fig. 2c). No NAL inhibition of phage promoter directed synthesis was observed in the *nalA*^r *E. coli* strain in conditions where total inhibition is seen in the isogenic *nalA*^s strain (Fig. 2a). This shows the NAL-target protein involved in transcription is the same protein involved in DNA replication.

The recently isolated *nalA* protein participates in DNA gyrase mediated reactions^{1,10,13,14}. Since this enzyme is also inhibited by coumermycin and novobiocin, we examined the

Table 1 Nalidixic acid inhibition of *trp* mRNA synthesis

	Anti-biotic	Tryptophan (50 μg ml ⁻¹)	<i>trp</i> mRNA (% of total RNA)	Specific activity of ³ H-RNA (c.p.m. per mg)
Phage promoter directed synthesis (strain AE1)	None	+	1.17	5.8 × 10 ³
	NAL	+	0.12	6.3 × 10 ³
	CAP	+	3.01	5.6 × 10 ³
P _{trp} directed synthesis (strain AE1 (h ⁺ i ⁸⁰))	None	—	3.02	3.3 × 10 ³
	NAL	—	3.48	1.3 × 10 ³
	CAP	—	0.18	3.0 × 10 ³

E. coli strain *trpAE1* or its lysogen *trpAE1* (h⁺i⁸⁰) was infected with ϕ80_{trp} phages and incubated at 30 °C in the presence or absence of L-tryptophan (50 μg ml⁻¹), respectively. NAL (40 μg ml⁻¹) or chloramphenicol (CAP; 100 μg ml⁻¹) was added at the 8th minute of incubation after the phage infection. Pulse-labelling was carried out with 100 μCi of ³H-uridine for 1 min starting 29.5 min after infection. The value of *trp* mRNA hybridised with λ_{trp} DNA is expressed as a percentage of total labelled RNA added into a hybrid assay system and is the average of duplicate determinations. The value of λ DNA background was subtracted from each hybrid value. Details for procedures used in these experiments are described elsewhere³⁹.

effect of these antibiotics on ASase synthesis. The inhibition of P_{trp} and phage promoter directed ASase synthesis by different doses of novobiocin and coumermycin (Fig. 3b, c) show a striking parallel with NAL inhibition. In all cases P_{trp} directed synthesis is much less sensitive to these antibiotics than phage promoter directed ASase synthesis. The 20% inhibition of P_{trp} directed ASase synthesis at 100 μg ml⁻¹ novobiocin probably reflects inhibition of DNA replication observed at this dose level in this strain (see ref. 28). The greater inhibition observed with coumermycin could be due to the greater permeability of *E. coli* to this antibiotic¹¹.

Our results provide the first direct evidence that DNA gyrase is involved in transcription. Three other antibiotics known to be specific inhibitors of DNA gyrase mediated supercoiling dis-

Fig. 5 Effect of nalidixic acid on the stability of *trp* mRNA synthesised from a phage promoter (a) and the authentic *trp* promoter (b). At 30 °C strain *trpAEl* (a) or strain *trpAEl* (h⁺) (b) was infected with $\phi 80trp$ in the presence of (a) or absence of (b) L-tryptophan (50 $\mu\text{g ml}^{-1}$), respectively. Pulse-labelling (1 min) carried out with 33 $\mu\text{Ci ml}^{-1}$ ³H-uridine at the 15th minute after the phage infection was immediately followed by addition of rifampicin (300 $\mu\text{g ml}^{-1}$) in the presence of (○) or absence (●) of 40 $\mu\text{g ml}^{-1}$ NAL. At the times indicated portions of the cultures (6×10^9 cells) were removed for RNA extraction. The *trp* mRNA values are expressed as ³H-RNA hybridised per μg RNA and normalised to 100% for the maximum value. The value represented is the average of duplicate determinations. Detailed procedures are described elsewhere³⁹.

played the same promoter specific inhibition of transcription as NAL. The specificity implies that transcription requires DNA gyrase when initiation occurs at the phage promoter but not when initiation occurs at the *trp* promoter. In addition, it seems that it is the supercoiling activity of DNA gyrase that is involved in transcription. The effectiveness of these inhibitors on phage promoter-directed transcription is striking when compared to the inhibitor concentration required to obtain an equivalent degree of inhibition of DNA synthesis.

The origin of the specific requirement of DNA gyrase for one of the two promoters remains unexplained. Botcham²⁹ observed an increase in early phage promoter mRNA synthesis in λ when supercoiled DNA template was used instead of a relaxed template. Although no studies have directly compared *P*_{trp} transcription on supercoiled and relaxed templates, it is possible that by raising the superhelix density DNA gyrase could preferentially assist a weak promoter at binding RNA polymerase. This simple mechanism would be consistent with suggestions that complex formation between RNA polymerase and a promoter is accompanied by duplex unwinding^{30,31}. However, the DNA gyrase-requiring promoter seems to be stronger than the *P*_{trp} promoter when total enzyme activity is examined. It is difficult to explain this simply by considerations of superhelix density.

As an alternative it is tempting to speculate that the critical factor in determining the requirement for DNA gyrase is the linking of transcription with translation^{23,24}. The phage promoter which requires DNA gyrase is not linked to translation whereas the gyrase-independent promoter is linked to translation. Clearly, further studies are needed to determine whether

it extends to other host cell translational-independent promoters.

Another alternative hypothesis is that the phage promoter is subject to some type of topological constraint which DNA gyrase must overcome in order for transcription to occur. For example the phage promoter could be involved in a loop of DNA where the ends were held rigid by attachment to a cell constituent such as the cell membrane. Such a loop structure had been postulated for the *E. coli* chromosome^{32,33}.

In λ phage it has been reported that transcription initiated at the leftward phage promoter is dependent on the phage N protein³⁴⁻³⁷. This protein interacts with RNA polymerase and DNA so that in the presence of the rho termination factor, the RNA polymerase no longer recognises a termination point present in the phage genome³⁸. Transcription of the *trp* operon in $\phi 80$, is dependent on the phage N gene product, as the operon is integrated into the phage at a point past the rho termination site. Therefore, it is possible that NAL is acting as an anti-N effector, so that phage transcription in the presence of the drug is terminated at the rho site. However, in preliminary experiments, NAL inhibition of phage controlled ASase synthesis has been observed in $\lambda ptrp$ phages lacking the rho dependent termination site (data not shown).

Although it is not clear how *pnaI* participates in RNA synthesis, it is obvious that the transcriptional apparatus at some operons is dependent on the *pnaI* protein. Thus, NAL and *pnaI* can serve as a probe to examine the transcriptional process at least in the case of phage promoter synthesis and perhaps in bacterial transcription.

We thank Dr Michio Oishi for helpful discussions and Ms J. Tamayo for preparing the manuscript. This work was supported by a grant from NIH (GM21073) to Michio Oishi. C.L.S. is the recipient of a PHS Postdoctoral Fellowship (GM95460).

Bacteriophages inhibit degradation of abnormal proteins in *E. coli*

Lee D. Simon & Kathleen Tomczak

On infection of Escherichia coli cells by bacteriophages T4, T5 or T7, the degradation of E. coli protein fragments and abnormal proteins is inhibited. Normal E. coli proteins, however, continue to be degraded at their usual rates. T4 early protein(s) is needed to inhibit the turnover of abnormal proteins in T4-infected E. coli cells.

HALF LIVES of proteins with abnormal conformations and protein fragments are much shorter than those of most normal proteins in bacterial and in eukaryotic cells^{1,2}. Most nonsense fragments of *Escherichia coli* proteins are so short-lived that either they fail to accumulate to detectable levels or they are found in much lower quantities than wild-type proteins^{3,4}. *E. coli* polypeptides containing missense alterations also tend to turn over rapidly compared to normal proteins⁵. Nonsense fragments of virus proteins from bacteriophage T4-infected *E. coli* cells are, in contrast, often found at levels approximating those of normal T4 proteins⁶. In this article we present evidence relating to the basis for this difference in stability between *E. coli* and T4 protein fragments.

The identities and functions of the specific enzymes responsible for the rapid turnover of abnormal proteins and protein fragments are not known in detail, but some information of interest is available about this system in *E. coli*. The degradation of such proteins is ATP-dependent². If cellular ATP levels are substantially reduced, the turnover of abnormal proteins and protein fragments is also reduced⁷⁻⁹. To investigate the characteristics of this degradative system, the intracellular levels of abnormal proteins can be increased by treating cells with puromycin, leading to the production of protein fragments, or with amino acid analogues, leading to the production of full-sized proteins with abnormal conformations. In *E. coli*, both puromycyl peptides and analogue-containing proteins are degraded by an ATP-dependent system^{2,7,8}, as are other abnormal proteins and protein fragments. Specific mutations called *deg*⁻ (or *lon*⁻) at 11.4 minutes on the *E. coli* map, near *proC*, reduce the turnover rates of protein fragments¹⁰, abnormal proteins, and also of phage λ proteins containing temperature-sensitive, missense alterations¹¹. The molecular basis for the effect of *deg*⁻ mutations on the *E. coli* degradation system is obscure.

The mechanism by which the *E. coli* degradation system recognises abnormal proteins is also obscure. Electron micrographs suggest that abnormal proteins, if present in sufficient quantity, form intracellular aggregates which appear adjacent to the *E. coli* inner membrane^{12,13}. The ATP-dependent degradative activity is probably bound to the *E. coli* cell membrane (R. Voellmy and A. L. Goldberg, personal communication). The adherence of abnormal proteins to the cell membrane, probably through exposed hydrophobic regions of the proteins, may provide the recognition signal for the degradation system. It may be of interest, therefore, that the earliest detectable step in T4 capsid assembly involves the formation of amorphous aggregates of unprocessed capsid proteins on the cell membrane¹⁴. These aggregates are morphologically indistinguishable from those formed by abnormal *E. coli* proteins¹. Yet, if these T4

proteins were degraded, the production of progeny virions could not occur. The mechanism by which T4 proteins probably avoid the *E. coli* degradation system is described below.

Degradation of *E. coli* proteins and puromycyl peptides after T4 infection

To study the effects of bacteriophage infection on the degradation of abnormal *E. coli* proteins and protein fragments, we first examined the degradation of puromycyl protein fragments (PPF) in uninfected and in T4-infected *E. coli* CR63 cultures. We exposed a CR63 culture to ¹⁴C-leucine in the presence of puromycin; the unincorporated puromycin and ¹⁴C-leucine were then removed and the cells were resuspended in fresh medium with unlabelled leucine. The culture containing the ¹⁴C-PPF was divided into two equal volumes. T4 particles in tryptone broth were added to one volume of cells and sterile broth was added to the other. Samples taken before the culture was divided and at various times thereafter were added to cold trichloroacetic acid (TCA) at a final TCA concentration of 5% to precipitate high molecular weight polypeptides. As ¹⁴C-PPF are degraded to amino acids which are soluble in TCA the corresponding radioactivity appears in the TCA supernatant. The fraction of the ¹⁴C-leucine that was TCA-insoluble before dividing the culture, but that became TCA-soluble afterwards is referred to as the percentage of protein degraded.

The amount of protein degraded in the uninfected cultures varies as a function of the puromycin concentration used during the labelling period (Fig. 1). When no puromycin is added to the culture, 4% of the ¹⁴C-labelled proteins is degraded in 30 min; in the presence of 15 $\mu\text{g ml}^{-1}$, puromycin protein degradation in 30 min increases slightly to 5%; 50 $\mu\text{g ml}^{-1}$ puromycin produces a level of 14% protein degradation; and 100 $\mu\text{g ml}^{-1}$ puromycin 24%. The correlation between increasing concentrations of puromycin and increasing levels of protein degradation is expected; as the concentration of puromycin is increased there is an increase in the production of protein fragments that are turned over rapidly relative to normal proteins that are turned over slowly.

Although bacteriophage T4 infection has no detectable effect on the degradation of normal *E. coli* proteins (Fig. 1a), T4 infection drastically inhibits the degradation of ¹⁴C-PPF (Fig.

Table 1 PPF degradation after infection by T4, T5 or T7 phages

Culture*	% Protein degraded†
Uninfected	14
T4-infected	9
T5-infected	10
T7-infected	11

* *E. coli* B cultures growing at 37°C.

† The % of PPF degraded during the first 15 minutes after infection (or the comparable time interval for the uninfected control). Normalised data from two experiments are presented. Comparisons of PPF degradation at later time intervals are precluded by the short T7 latent period.

Fig. 1. Degradation of normal proteins and of puromycin protein fragments (PPF) in uninfected and in T4-infected *E. coli* CR63 cells. Puromycin ($0\text{--}100\text{ }\mu\text{g ml}^{-1}$) was added to mid-log phase CR63 cultures (5×10^8 cells per ml) in M9 medium¹⁶; 10 min later ^{14}C -leucine ($0.2\text{ }\mu\text{Ci ml}^{-1}$) was added. After a 5 min labelling period, the bacteria were collected on Millipore filters and washed twice to remove unincorporated puromycin and ^{14}C -leucine. The bacteria were then resuspended in fresh medium containing

unlabelled leucine ($300\text{ }\mu\text{g ml}^{-1}$). The cultures were divided and one half of each was infected with wild type T4 D particles. Unless otherwise stated, the multiplicity of infection in this and in other experiments was 5 phage per cell, and the T4 particles used were wild type T4 D. Samples taken just before the cultures were divided (our 0-time samples) and at various times thereafter were added to cold TCA at a final TCA concentration of 5%. The TCA insoluble and soluble materials were separated from each other by low speed centrifugation. The amounts of ^{14}C -leucine in the TCA supernatants and pellets were determined by liquid scintillation counting techniques. The pellets were dissolved with Soluene (Packard) and then counted in BBOT scintillation fluid; aliquots of the supernatants were counted in Patterson Greene scintillation fluid⁷. The fraction of the ^{14}C -leucine that was TCA insoluble before dividing the culture, but that became TCA soluble afterwards is plotted as the percent of protein degradation. The arrows in this and in subsequent figures indicate the times when phages or other treatments were added to the bacterial cultures. *a*, No puromycin; *b*, $15\text{ }\mu\text{g ml}^{-1}$; *c*, $50\text{ }\mu\text{g ml}^{-1}$ and *d*, $100\text{ }\mu\text{g ml}^{-1}$ puromycin.

1*b*, *c*, *d*). Thus the degradation to acid soluble material of proteins made in the absence of puromycin is quantitatively similar in the T4-infected and in the uninfected cultures. As the concentration of puromycin increases, causing the production of progressively more PPF, the T4-induced inhibition of PPF degradation becomes apparent.

Degradation of normal and canavanine-containing proteins after T4 infection

To determine whether T4 infection inhibits the degradation of abnormal proteins other than puromycin protein fragments and to extend our observations of normal protein turnover after T4 infection, we performed the following double label experiment. Normal proteins in *E. coli* A-33, an arginine auxotroph, growing in the presence of arginine were labelled with ^3H -lysine; after a suitable labelling period, unincorporated ^3H -lysine and arginine were removed, and the growth medium was supplemented with unlabelled lysine and L-canavanine; 5 min later ^{14}C -leucine was added to label the abnormal canavanine-containing *E. coli* proteins (CCP). At the end of the labelling period, the cells were collected, washed free of unincorporated canavanine and ^{14}C -leucine, and then resuspended in medium containing arginine and unlabelled leucine. Degradation of the ^3H -normal proteins and ^{14}C -abnormal canavanine-containing proteins was measured in the T4-infected and in uninfected control cultures. The results of this experiment (Fig. 2) show no detectable difference in the degradation of normal ^3H -proteins between the T4-infected and uninfected cultures. Yet, in the same cells the degradation of abnormal ^{14}C -proteins is severely inhibited in the T4-infected culture compared with the uninfected control. We conclude that during T4 infection, the rapid degradation of abnormal proteins and protein fragments is inhibited, but the turnover of normal proteins is unaffected.

Inhibition of protein degradation after infection by various multiplicities of T4 particles

If the processes of T4 adsorption and injection were themselves directly responsible for altering the cell in such a way that the degradation of PPF and CCP were inhibited, then the extent of inhibition of degradation might be expected to increase with

increasing multiplicities of infection (MOI). If, on the other hand, T4 proteins synthesised after phage adsorption and injection were responsible for inhibition of degradation, little change in inhibition would be expected from different MOIs since only about four infecting T4 genomes per cell can be expressed in normal conditions.¹⁷ We therefore infected

Fig. 2 The degradation of proteins in uninfected and in T4-infected *E. coli* A-33 cells containing both ^3H -normal proteins and ^{14}C -abnormal proteins. Normal proteins in *E. coli* A-33 bacteria growing in M9 medium supplemented with L-arginine ($50\text{ }\mu\text{g ml}^{-1}$) and L-tryptophan ($50\text{ }\mu\text{g ml}^{-1}$) were labelled with ^3H -lysine ($1\text{ }\mu\text{Ci ml}^{-1}$); the cells were then collected on filters, washed free of ^3H -lysine and of arginine, and resuspended in M9 medium lacking arginine, but supplemented with L-canavanine ($20\text{ }\mu\text{g ml}^{-1}$) and unlabelled lysine ($300\text{ }\mu\text{g ml}^{-1}$). After 10 min ^{14}C -leucine ($0.2\text{ }\mu\text{Ci ml}^{-1}$) was added to label the abnormal CCP; 5 min later the cells were again collected on filters, washed, and resuspended in fresh M9 with arginine ($100\text{ }\mu\text{g ml}^{-1}$) and unlabelled leucine ($300\text{ }\mu\text{g ml}^{-1}$). Thus, the *E. coli* A-33 culture contained ^3H -normal proteins and ^{14}C -CCP. One half of the culture was infected with T4 particles; degradation of ^3H -normal proteins and ^{14}C -CCP was assayed as described in Fig. 1. The low level of degradation of ^3H -normal proteins observed in this experiment is a consequence of the elapsed time between labelling normal proteins and the onset of our degradation assays. Those normal proteins that turn over rapidly had been degraded during the labelling of CCP and, therefore, had become TCA soluble by the start of our protein degradation measurements.

Fig. 3 The effect of various multiplicities of T4 particles on the degradation of *E. coli* puromycyl protein fragments. This experiment is similar to that in Fig. 1d, except that after exposure to puromycin ($100 \mu\text{g ml}^{-1}$) the CR63 culture was split into several aliquots which were then infected with the indicated multiplicities of T4 phages.

aliquots of a CR63 culture containing ^{14}C -PPF with various multiplicities of T4 particles. As can be seen in Fig. 3, the inhibition of PPF degradation following T4 infection is not multiplicity dependent. The same level of inhibition was observed with MOIs of 3, 6, 10, and 15 T4 particles per bacterium. Thus, it seems that the processes of T4 adsorption and injection are not directly responsible for the inhibition of PPF degradation.

Requirement for T4 protein synthesis to inhibit degradation of abnormal proteins

To find whether T4 protein synthesis is needed to block the degradation of *E. coli* protein fragments we used the antibiotic chloramphenicol (CAP) to inhibit protein synthesis at various times after T4 infection. Puromycyl protein fragments in *E. coli* CR63 were labelled with ^{14}C -leucine, as described above; the culture was divided and one half was infected with T4 particles. Our data (Fig. 4) show that T4 protein synthesis is required to inhibit the degradation of ^{14}C -PPF. If CAP is added and T4 protein synthesis is blocked 1 min after the addition of T4 particles, the T4 infected and uninfected cultures show essentially no difference in PPF degradation. CAP does not interfere with T4 adsorption or injection; over 95% of the cells in the 1-min CAP sample had lost their colony-forming ability because of T4 infection. If CAP is added to samples at progressively later times after T4 infection, the samples show progressively more inhibition of PPF degradation. The degradation of PPF when CAP is added 7 min after infection is nearly the same as in the T4-infected sample with no CAP. The addition of CAP 10 min or longer after infection does not affect the inhibition of PPF degradation (data not shown). Therefore, it seems that T4 proteins synthesised early after infection inhibit the degradation of puromycyl peptides. Further, the continued synthesis of these proteins is not necessary to sustain the inhibition for the duration of the latent period.

Maturation-defective T4 mutants¹⁵ have also been used to demonstrate that T4 early proteins are sufficient to inhibit PPF degradation. The proteins encoded by T4 genes 33 and 55 are required continuously for the synthesis of late T4 mRNA; thus, in T4 33⁻ or 55⁻ infections only early proteins are produced.

Our results (Fig. 5) show that in T4 33⁻ or 55⁻ infected *E. coli* cells PPF degradation is inhibited to the same extent as in the control T4 infection. We conclude that inhibition of PPF degradation is an early T4 function.

The extent of T4-induced inhibition

It is difficult to assess with certainty the extent to which T4 inhibits CCP and PPF degradation. The continued solubilisation of labelled proteins that we have observed after T4 infection is at least in part due to (1) the time required for T4 particles to adsorb to bacteria, to inject their DNA, and to effect maximum

Fig. 4 The requirement for T4 protein synthesis to inhibit degradation of puromycyl protein fragments. This experiment is similar to that described in Fig. 1d, except protein synthesis was blocked at 1 min (○), 4 min (▲), 5 min (□), 6 min (●), and 7 min (△) after T4 infection and immediately after dividing the CR63 culture in one of the uninfected controls (●) by addition of chloramphenicol (CAP) at a final concentration of $100 \mu\text{g ml}^{-1}$. ×, Uninfected control; 0, infected control.

inhibition, (2) the uninterrupted turnover of those normal proteins synthesised along with PPF or CCP during the labelling period, and (3) continued cleavages by peptidases of CCP and PPF molecules that were substantially degraded before T4-induced inhibition became effective. As treatment of cells with organic solvents such as toluene virtually eliminates the degradation of β -galactosidase amber fragments (D. Zipser, personal communication), we were interested to compare the inhibition of PPF degradation observed after treatment with organic solvents to that observed after T4 infection (Fig. 6). The organic solvent used was chloroform, which blocks degradation as rapidly as any treatment we have tested. Our results indicate that addition of chloroform to *E. coli* cells inhibits PPF turnover only slightly more rapidly than does addition of T4 particles (MOI = 5). This difference in kinetics of inhibition is probably due to the longer time required by T4 to maximally block PPF degradation. The turnover rates of PPF in the T4 infected and chloroform treated samples are nearly the same by 10 min after infection.

Inhibition of protein degradation by T5 and T7 phages

Inhibition of degradation of abnormal proteins and protein fragments following virus infection is not peculiar to T4 phages. Other phages, unrelated to T4, such as T5 and T7, also inhibit PPF degradation (Table 1). Neither T5 nor T7 infection, however, seems to inhibit PPF breakdown to as great an extent as does T4 infection.

Implications

We have found that infection by T4, T5, or T7 bacteriophages results in the inhibition of degradation of abnormal *E. coli* proteins (CCP) and puromycyl protein fragments (PPF). Normal *E. coli* proteins, however, continue to turn over at their usual slow rates despite T4 infection. The differential effects of T4 on the turnover rates of normal and of abnormal proteins are not explained by the model of one *E. coli* proteolytic system in which the V_{max} of a crucial degradative enzyme is reduced after phage infection so that at high substrate concentration (for example, in the presence of PPF or CCP) the reduced V_{max} becomes rate limiting, whereas at low substrate concentrations (in the absence of PPF or CCP) substrate is limiting. On the contrary, our experiments (Fig. 2) show that in the same T4-

Fig. 5 Inhibition of PPF degradation after infection by T4 maturation defective mutants. This experiment is similar to that described for Fig. 1d with the following exceptions: an *E. coli* B (*Lon*⁻) culture containing ¹⁴C-PPF was divided into four aliquots, one of which was infected with T4am N134 (gene 33⁻) (○), another with T4am BL292 (gene 55⁻) (▲), the third with wild type T4 particles (□), and the fourth was treated only with broth (●). Degradation of ¹⁴C-PPF in each aliquot was assayed as described in Fig. 1.

Fig. 6 The effect of chloroform on degradation of PPF. This experiment is similar to that described for Fig. 1d, except that several drops of chloroform were added to one aliquot of the ¹⁴C-PPF-containing *E. coli* CR63 culture. ●, Treatment with broth only; ○, T4 infection only; ×, chloroform added.

infected cells at the same times that CCP (or PPF) degradation is inhibited, the degradation of normal proteins is unaffected. Thus, high substrate concentrations are not related to the differential effects of T4 infection on the degradation of normal and of abnormal proteins. Our results suggest that, at least in part, the *E. coli* pathway for the degradation of abnormal proteins is distinct from the pathways for the degradation of normal cellular proteins. Therefore, the turnover of most normal *E. coli* proteins is not a consequence of changes in these proteins which renders them susceptible to degradation as abnormal proteins.

Our observations explain why nonsense fragments of most T4 proteins are readily found in extracts of infected cells⁶, whereas *E. coli* nonsense fragments are usually not found due to their rapid degradation in uninfected cells. This difference in turnover rates is not the result of some intrinsic distinction between T4 and *E. coli* proteins, but rather of the inhibition of CCP and PPF degradation following T4 infection.

Inhibition of CCP and PPF degradation requires T4 protein synthesis. Adsorption of T4 particles to the *E. coli* surface and injection of T4 DNA are not by themselves sufficient to alter protein turnover. The results of experiments using chloramphenicol to block T4 protein synthesis at various times after infection suggest that an early T4 function is responsible for inhibition of CCP and PPF degradation. This suggestion is consistent with our observations following infections by T4 maturation defective mutants. In T4 33⁻ or T4 55⁻ infection, early proteins, but no late proteins, are made; nevertheless, degradation of CCP and PPF is inhibited to the same extent as in wild type T4 infection. We conclude, therefore, that early T4 protein(s) shut off the *E. coli* system for degradation of abnormal proteins and protein fragments.

The fact that several unrelated phages are able to inhibit CCP and PPF degradation in their host cells suggests that this ability may have some evolutionary significance for the survival of these phages. Perhaps specific proteins of various phages and

other viruses would be degraded as though they were abnormal proteins by the host cell if its degradation system were not inhibited.

letters to nature

An ultraviolet subdwarf companion to HD17576

ULTRAVIOLET objects detected by the S2/68 UV sky-survey telescope¹ aboard the TD-1 satellite consist primarily of known early-type stars. In addition, there is a substantial subgroup of unidentified and/or untyped ultraviolet stars including some new hot subdwarfs^{2,3} and a small subgroup of known late-type objects including the 20 stars of types F and G listed in the Ultraviolet Bright-Star Spectrophotometric Catalogue⁴. Selection of those objects whose ultraviolet colours suggest that they are earlier than an unreddened B5 V star ought to eliminate the latter category entirely, but several apparently late-type anomalies persist. If these objects cannot be discarded on grounds of blending, misidentification, inaccurate ultraviolet colours (objects with low flux or few orbital passes), or erroneous prior spectral types taken from the literature, then one is confronted with the possibility of genuine duplicity. UV0246-37, taken from the UCL Catalogue of Ultraviolet Objects soon to be published, is just such an object: a binary system consisting of a previously unrecognised hot ultraviolet star and a cooler G-type primary which wholly dominates in the visible region.

Six unblended spectral scans of UV0246-37 were obtained by the S2/68 experiment in 1972-3, two of which must be rejected: in one pass the target lay too far off-centre to yield reliable data, and in the other the data were contaminated by the enhanced radiation background of the South Atlantic Anomaly⁵. Photon pulse counts were obtained in three 400-Å spectrometer channels centred on 1,550 Å (A2), 1,950 Å (A3), and 2,350 Å (A4), and in a photometric channel with FWHM 310 Å centred on 2,740 Å (A1 channel). These counts were converted to flux densities through the absolute calibration determined by Humphries *et al.*⁶ The mean ultraviolet spectrum from the four passes is plotted in Fig. 1, excluding the data at 1,750 Å and 2,150 Å where vignetting was severe. The steep blueward rise is reflected in the mean difference between the magnitudes derived from pulse counts in the A1 and A2 channels: $\overline{m_{A2} - m_{A1}} = -2.00$.

The position of UV0246-37 coincides with that of HD17576 (=DM-37° 1050 = SAO193923), a star of $m_{pg} = 8.1$ classified as G0 on two HD plates⁷. To verify the spectral classification and check for evidence of duplicity, uvby and β photometry was conducted on the 1-m telescope at the South African Astronomical Observatory in July 1977; and spectra at reciprocal dispersion 30 Å mm⁻¹ (second-order blue) were obtained on backed Ila0 plates with the f/1.4 EMI image-tube spectrograph at Cassegrain focus on the 1.9-m telescope in September 1977.

The luminosity class of the G0 star—as predicted among other factors on the strength of the G band, the dominance of Hδ over the Fe I and Sr II lines shortward of it, and measures of luminosity-sensitive line ratios⁸—must be V or IV-V. The only spectroscopic trait indicative of the presence of a hot companion is the ratio of the Ca II lines (K:H ≈ 3:4), long held to be a reliable diagnostic of a composite spectrum⁹ when the 'cool' primary is later than type F and the secondary earlier than type A.

The composite nature of HD17576 is strikingly confirmed by the uvby photometry (for a description of the uvby system, including the passbands of the four filters, see ref. 10):

$$\begin{aligned} V &= 7.82 \pm 0.02; u - b = 1.152 \pm 0.006 \\ b - y &= 0.382 \pm 0.006; m_1 = 0.128 \pm 0.010 \\ c_1 &= 0.113 \pm 0.010; \beta = 2.584 \pm 0.007 \end{aligned}$$

(weighted means of three observations). Since m_1 is low and c_1 very low indeed compared with the approximate mean values (for G0 V) of 0.18 and 0.34 respectively (E. Oblak, personal communication and ref. 11), it stands out conspicuously in a plot of the reddening-insensitive indices [c_1] against [m_1] (Fig. 2). On the other hand, $(b - y) = 0.382$ is not anomalous and though not a reliable luminosity discriminant further supports the G0 V classification of HD17576 since $(b - y)$ remains virtually unaffected by any faint hot companion. [$u - b$] = [c_1] + 2[m_1] = 0.369 is certainly bluer than normal (~0.76); had it not been

Fig. 1 Mean ultraviolet spectrum of UV0246-37 from the S2/68 experiment: nine unvignetted points in the wavelength region covered by the spectrophotometer channels (A2, A3, and A4) and the photometric datum at 2,740 Å (A1 channel). Ordinate units are 10^{-12} erg cm⁻² s⁻¹ Å⁻¹; abscissa units, Å. Error bars indicate the 1σ deviation over four of the six recorded orbital passes (see text).

contaminated, it could well have served as a luminosity discriminant¹¹. The H β measurement is slightly low (Crawford¹² tabulates 2.606 as the norm for G0) but among the G stars the β index loses most of its usefulness as a luminosity or temperature discriminant through the crowding of absorption lines.

The presence of the ultraviolet star in a binary system with a normal late-type primary enables us to infer the absolute luminosity of the hot secondary. The standard luminosity calibration gives $M_v = 4.4$ for a main-sequence G0 star^{13,14}; with $m_v = 7.82$, the distance turns out to be only ~ 50 pc.

On the absolute flux calibration scale determined for Vega by Hayes and Latham¹⁵, the apparent magnitude of UV0246–37 at 2,740 Å is $m_{A1} = 8.07$. To derive m_v for the hot secondary, the UV flux curve can be extrapolated—a possibly reprehensible procedure in view of the 0.2 or 0.3 mag uncertainty incurred by the Balmer jump—to give $(m_v - m_{A1}) = 2.0$. Alternatively, we can use the fact that the flux distribution of UV0853+01, an early-type field star unaffected by the presence of a cool companion, mimics that of UV0246–37 to infer the same 2.0 mag difference. Moreover, if the mean value $\overline{m_v - m_{A1}}$ is calculated for all hot subdwarfs (J. R. Giddings, unpublished data) with ultraviolet colours $(m_{A2} - m_{A1})$ and $(m_{A2} - m_{A4})$ deviating no more than ± 0.2 from those for UV0246–37, we arrive once more at the same result.

Fig. 2 Boundaries of the main sequence in the $[c_1]$ – $[m_1]$ plane, with normal positions for several spectral types shown. In standard notation¹⁰, $[c_1] \equiv c_1 - 0.20(b - y)$ and $[m_1] \equiv m_1 + 0.18(b - y)$. The diamond represents HD17576, whose anomalous position reflects its composite nature. The main-sequence band is based on the observational material of Oblak *et al.*¹¹.

Thus $m_v \approx 10.1$ for the secondary and its absolute magnitude follows: $M_v = 6.7$. If the determination of MK luminosity were in error by half a class interval, a not uncommon discrepancy¹⁶, then the quoted value could be 0.6 mag too faint. In any case it is at once evident that the secondary is markedly subluminal for an early-type star albeit more luminous than any white dwarf; it is indeed a hot subdwarf akin to such objects in the UCL Catalogue as UV1758+36 (ref. 2), UV0921+36 (BD +37° 1977) (refs 17–19), and UV2158–02 (BD –3°5357) (ref. 20) but far more subluminal. Nevertheless, it is not without precedent: four objects in the list of subdwarf O stars by Greenstein and Sargent²¹ (HZ 38, HZ 3, Feige 26, and BD +25°4655) have $M_v \geq 6.0$. Luyten²² considers the kinematic data for O and B subdwarfs scarcely distinguishable and accordingly treats them as a single group for which, on the basis of his proper-motion survey of faint blue stars, he finds $\overline{M_v} = 4.1$. Evidently UV0246–37 has an exceptionally low luminosity, even for a subdwarf, indeed approaching that of the most luminous white dwarfs. However, the values of M_v for the hottest white dwarfs are ill determined: for HZ 43, assigned $M_v = 7.1$ by Greenstein and Sargent²¹, a careful study by Margon *et al.*²³ finds $M_v = 9.1 \pm 0.5$. Subdwarfs are in any case readily distinguished from white dwarfs on photometric and spectroscopic criteria (for example, ref. 24) except in a special case like the present one where the required observational data cannot be simply ascertained.

At this stage, estimation of the physical parameters of UV0246–37 is an invidious task inasmuch as the errors in the flux measurement are substantial and T_{eff} estimates from a black-body model are notoriously sensitive to the slope (for example, ref. 23). A crude black-body fit yields a temperature of $4.2^{+0.5}_{-0.7} \times 10^4$ K. It may be noted that HZ 38, an O subdwarf with the same luminosity²¹ as the one at hand, has $T_{\text{eff}} = 36,000$ K and $\log g = 7.0$.

The significance of the discovery reported here is twofold. Carnochan *et al.*¹⁷ have mustered evidence from the faint (limiting $m_v \sim 10$), unclassified ultraviolet objects detected by S2/68 that there exists a substantial population of subluminal hot stars in a region of the HR diagram previously considered sparsely populated. Their space density and scale height have been calculated and will be published elsewhere. UV0246–37 is manifestly drawn from this population.

Second, there is a growing body of recognised cool stars with hot secondaries^{20,25,26}, few of which represent such extreme cases of spectral segregation as UV0246–37, the primary being undetectable in the ultraviolet region and the presence of the secondary nearly indiscernible in the visible. The S2/68 survey yielded several other late-type ultraviolet anomalies of which ground-based spectroscopy and photometry are being carried out (ref. 27 and J. P. Swings and M. Berger, personal communications), and it is anticipated that other cool stars will prove to have unsuspected hot companions. These objects are prime candidates for investigation by the International Ultraviolet Explorer satellite since their fortuitous occurrence in binary systems will help to elucidate the nature of the hot subdwarfs.

We thank D. J. Carnochan and J. R. Giddings for discussions and assistance in data reduction. The hospitality of the South African Astronomical Observatory and the Royal Greenwich Observatory is acknowledged. This work was supported by the SRC and by a Royal Society Radcliffe Lectureship to J.D.

The origin of lunar palaeomagnetism

THE new determination of magnetic field anomalies over part of the Moon's surface from Apollo 15 and 16 subsatellite magnetometer data has recently been interpreted¹ in terms of magnetised areas of the lunar surface. I show here that, from this analysis, palaeomagnetic pole positions can be calculated and that these are so clustered on the lunar surface that there is evidence against meteoritic or cometary processes as explanations of the remanent magnetisation of the Apollo rocks. I conclude, therefore, that the Moon had a magnetic field in its early history produced by dynamo processes in a fluid electrically conducting core.

Since the discovery of remanent magnetisation of Apollo 11 lavas², we have attempted in a series of papers to interpret lunar palaeomagnetism as observed in the remanent magnetisation of the returned Apollo crystalline rocks and breccia and in widespread crustal magnetic anomalies mapped by magnetometers on Explorer 35³ and the Apollo 15 and 16 subsatellites⁴, and by the reflected electron technique⁵. Surface traverses of Apollo 14 and 16⁶ also detected magnetic anomalies. Our interpretation supposed that the Moon once had a magnetic field in which these rocks acquired, at the time of their cooling from above the Curie point of their iron grains, a stable thermoremanent magnetisation. This field existed at least from 4,000 to 3,200 Myr (the ages of the rocks studied), decreased from 1G to 5,000 nT (ref. 7) over this interval and has now disappeared. Much scepticism has been expressed⁸ about this hypothesis of an ancient internal field, presumably because a number of consequences follow which had not been envisaged by the majority of lunar scientists—the existence of a sizeable iron core in which a dynamo process can take place⁹, the melting of the entire Moon¹⁰ in its earliest history (so that the iron core formed) and thermal convection in the interior.

Consequently there have been several suggestions as to how the magnetisation of the lunar rocks might have been acquired by an external field¹⁰ (or no field at all, although as T. Gold points out, some far-reaching modification in physics, for example, the law of parity, would seem to be necessary if this explanation were to be sustained). These ideas appeal to processes with which we are unfamiliar in terrestrial studies, and they are therefore difficult to test. For example, the ubiquity of large meteorite impacts on the early lunar crust has suggested the possibility of impact magnetisation^{12,13}. Also it has been pointed out that cometary impacts are statistically likely to have been quite frequent on the Moon and again the physical processes during such events may have favoured magnetisation¹⁴. What must be postulated is that the acquisition of a stable remanent magnetisation is greatly facilitated during such large impacts either by the effect of the transient stress field on the

iron grains (although the magnetisation direction might be biased by the stress) or through the shock wave raising the rock temperatures instantaneously to above the blocking temperature of the iron grains. Thus the magnetising field on such a hypothesis could be small and transient: it may arise from surges of electric current in the plasma during impact, 'pseudo-lightning strikes', or be the field of the solar wind, which does not remain constant for long. We are concerned with the early history of the Solar System when the solar wind field may have been much more intense than at present. The average solar wind field now lies in the ecliptic, therefore a magnetisation of the Moon along its rotation axis is implausible if the magnetisation was acquired very quickly as must be the case in an impact magnetisation process¹⁵. On the other hand, because of the Moon's rotation, a magnetisation in the ecliptic or the lunar equatorial plane is unlikely unless the magnetisation was acquired in a time much shorter than a month.

Very important interpretations of the lunar magnetic anomalies, as seen by the Apollo 15 and 16 subsatellites, which bear on these critical questions, have been made by Hood, Coleman and Russell¹. They show that these magnetic anomalies at altitudes of 100 km can be represented by 35 dipoles at the surface of the Moon and they calculate the strength and direction of these dipoles. Strangway¹⁶, and Dermott and Runcorn (unpublished) found that the largest magnetic anomalies of the lunar far side demand east-west directed dipoles for their explanation. Hood *et al.* show that the dipoles are not randomly directed in space but lie nearly in the equatorial plane of the Moon. However, they show that their directions, projected in this plane, are scattered, apparently randomly, through 180°. They conclude that this random feature is the explanation of the null result found in the determination of the present dipole moment of the Moon¹⁷. This result I had explained¹⁸ by showing that a spherical shell permanently magnetised by a field of internal origin, so that the magnetisation is parallel and proportional to the field, which later disappears, produces no external field. I had argued that such magnetic anomalies would arise from the large craters releasing lines of magnetic force from the magnetised lunar shell. Thus the anomalies should be well modelled by a dipole in the centre of the crater but it has been often found in such attempts (ref. 1 and Dermott and Runcorn, unpublished) that the dipoles are not so positioned, although the largest magnetic anomalies are associated with the large craters around Van de Graaf on the far side. It therefore seems likely that the magnetised areas may sometimes result from the cooling of layers of breccia thrown out by meteoritic impacts, as suggested by Strangway *et al.*¹⁶.

The two features of the distribution of dipole directions, that they are near to the lunar equator and in that plane are randomly directed, seem to suggest that a field is responsible which is directed in this plane and this suggests the solar wind field which, though fluctuating, is on average in the plane of the ecliptic, to which the lunar equator is inclined by only 1°. Cometary or

Fig. 1 Distribution of pole positions from lunar magnetic anomaly dipoles (given in Table 1 of ref. 1). Stars are mean directions and circles the 95% circles of confidence. Stereographic projection of eastern (a) and western (b) hemispheres of Moon. The numbers are the dipole strengths per unit area given in G cm. Left, eastern hemisphere. Right, western hemisphere.

Table 1 Number of poles within 30° sectors of longitude compared with number expected on the theory that the dipoles are randomly orientated in the lunar equatorial plane

Longitude sectors	No. of poles all included		No. of poles magnitudes <10 G cm excluded	
	Observed	Theory	Observed	Theory
Eastern Hemisphere				
0–30°, 150°–180°	2	3.1	0	2.3
30°–60°, 120°–150°	6	3.7	4	2.7
60°–90°, 90°–120°	7	6.0	7	5.9
Western Hemisphere				
180°–210°, 330°–360°	1	3.8	1	3.6
210°–240°, 300°–330°	4	4.5	4	4.2
240°–270°, 270°–300°	13	9.6	12	9.1

$\chi^2 = 5.30$ (all poles included) and 5.95 (excluding <10 G cm). Confidence limits for rejection of theory, 75% and 80% respectively.

meteoritic impact hypotheses seem to be supported. However, Table 1 of Hood *et al.*¹ gives the locations on the Moon of these dipoles and their angles of orientation to the vertical and the meridian are listed. I have calculated the corresponding pole positions, as has proved fruitful in palaeomagnetism, that is, the latitudes and longitudes of the axes of those dipoles at the centre of the Moon which have fields at the various locations coincident with the palaeofield directions¹⁹ found there. These poles are plotted in Fig. 1 and are seen not to be random. A minority of directions are opposed to the most frequent grouping: this is to be expected as a dipole may either arise from a magnetised body of rock or from a magnetised part of the lunar crust in which there is a demagnetised volume, a physical cavity formed by impact or a volume of rock demagnetised by impact. Moreover, reversals of polarity of a field produced by a core dynamo process is to be expected. The scatter of the pole positions is considerable but this is to be expected as many of the anomalies, so remarkably analysed and modelled by Hood *et al.* are much less than 1 nT, and their treatment of the magnetometer data has required the removal of the much larger field of the Earth's magnetotail, which is not very constant. In fact the nonrandom distribution of the pole positions demonstrates that this difficult process has been successfully accomplished by Hood *et al.* and suggests that an attempt to separate the magnetic anomalies from other regions of the Moon, at present obscured by the solar wind field, might be worth attempting.

Thus the demonstration that the vector means of the two groups of pole positions, shown with their 95% circles of confidence in Fig. 1, are at 180°, seems at first sight to be strong evidence that the magnetisation of the lunar crust does not arise from meteoritic or cometary impacts, for the palaeomagnetic directions impressed on the lunar crust from such processes must, because of the lunar rotation, be instantaneous directions from the solar wind magnetic field. Unless all the impacts occurred at the same time of the month, the palaeomagnetic directions over the Moon as a whole would not have an axis fixed in one region of the Moon. However, the fact that the mean poles are along the E–W equatorial axis is odd. Consider a set of dipoles at a site (0° N, 180° E) lying in the equatorial plane. If the difference in azimuths of two neighbouring dipoles is dI then their poles lie on the equator at distance $d\theta$ apart where θ is the angular distance from the site

$$d\theta = dI(1 + 3 \cos^2 \theta)/2$$

Thus if these dipoles at one site are distributed randomly through 180°, then their poles are clustered four times more densely about an E–W equatorial axis than about the N–S axis. If random N–S components are added, this distribution would resemble that of Fig. 1. However, I show now that the conclusion that the dipoles are random is wrong, although clearly the dipole

directions will be substantially affected by random components inherent in the magnetic survey observations and analyses. It is significant that four out of six of those poles which lie far away from the main group have dipole moment per unit area magnitudes less than 10 G cm, that is corresponding to fields less than 0.1 nT at the subsatellite orbit.

The sites of the dipoles are in fact distributed over a strip 45° on either side of the mean site at 10° S 180° E. If random dipoles were uniformly distributed over the equator between 135° E and 215° E then the pole density distribution would be proportional to $\tan^{-1} \sec 2\theta$, with a maximum at 90° E and 270° E, three times that of the minimum at 0° and 180°.

On the above hypothesis the proportion of poles within the 30° ranges of longitudes is shown in Table 1 and is compared with the actual number. It is clear that χ^2 test excludes at the 80% confidence level the hypothesis that the directions are wholly random: an east–west component is also present.

Yet there is an external field to which the Moon is exposed during 2–3 days around full Moon and which is directed along the Earth–Moon line. This is the Earth's magnetotail: the Moon traverses both its north and south lobes, in which the magnetic field is directed towards and away from the Sun respectively, in the course of the year. Thus if impacts had imparted to crustal regions magnetisations directed along this field, a plot resembling Fig. 1 would be found. However, the Moon spends 10 times as long in the solar wind as in the magnetotail, and so unless impacts occurred always at full Moon the crustal magnetisations should be nearly randomly distributed in the ecliptic. This hypothesis would, if 90° of rotation of the Moon about its axis since magnetisation had occurred, explain the results of Table 1, had the magnetised area been small. But for two areas of longitude difference $d\lambda$ within the strip, imprinted by the magnetotail field, their calculated pole positions would be $d\theta$ apart where $d\theta = 3d\lambda(2 + \tan^2 \lambda)/(4 + \tan^2 \lambda)$. This pole distribution is spread nearly uniformly over about 70° on either side of the mean pole. Thus the additional hypothesis of magnetisation by the magnetotail field, as well as the solar wind field, would broaden the pole distribution of the theory columns of Table 1, rather than reduce it as required by the observations.

So in spite of random scatter and the restricted area covered by the anomalies, it is concluded that the ancient pole position was not near the present axis of rotation of the Moon. Yet, in spite of the lunar core being an order of magnitude smaller than the Earth's core and the angular rotation less by a factor of 30, the reason originally advanced to explain the fact that the average geomagnetic field is directed along the axis of the Earth's rotation, that is the Coriolis force is many orders of magnitude greater than any other term in the hydrodynamic equation²⁰, must also apply to the Moon. Therefore, I conclude that lunar palaeomagnetism shows that polar wandering occurred in the Moon's early history, that is, the Moon rotated relative to its axis of rotation. It was shown previously that polar wandering can take place in a planet either by internal motion²¹ or by the disequilibrium produced by a mountain²² (or crater), provided that solid state creep in the interior can readjust the position of the equatorial bulge which otherwise strongly stabilises the rotation axis. The dates of the magnetised regions on the lunar highlands, which we are discussing, are very early²³: if the rocks are impact breccias they may be the same age as the last great impacts on the Moon (4.1×10^9 yr)²⁵ or, if they arise from craters in the already magnetised highlands crust, they may be older. In any case, they are of such an age that the great impacts which redistributed mass on the lunar surface on a large scale, were a likely cause of the polar wandering required to explain this result. Further studies when a complete magnetic anomaly map is obtained by the lunar polar orbiter may show pole positions distributed between the present equator and the present rotation pole. Such a polar wandering path would be of great interest, and would perhaps be useful for the relative dating of the lunar far side. Such a slow polar wandering through over 90° would suggest that solid state creep in the lunar interior has played an important part in its evolution and supports the

view that convection is responsible for its non hydrostatic shape, as I have maintained^{23,26}. The axis of minimum moment of inertia is aligned by the Earth so that the 'bulge' is earthward: thus if polar wandering has occurred it may have taken place along the present limb so that the ancient axis is now east-west.

I thank P. J. Coleman, S. F. Dermott, L. Hood, R. Lin, L. Molyneux and C. T. Russell for helpful discussions.

Short-term storage and wind power availability

IN a discussion on the economics of alternative energy sources, Ryle¹ suggested that wind power in conjunction with short-term thermal storage can provide a viable and attractive source of energy in the UK. Leicester, Newman and Wright² have recently analysed wind data and empirically derived heating demand over a six-month period. On the basis of these data they suggest that short-term (~150 h) storage is inadequate to provide a reasonably reliable supply from wind generators for heating purposes. This conclusion has been criticised by Diesendorf and Westcott³ and, in view of the limited data sample used it is clear that a more extensive analysis is required. Here we use hourly wind and temperature measurements over a 17-yr period (data obtained from the Meteorological Office, Bracknell) to investigate the performance of a simple system in which wind power is used in conjunction with 150-h thermal storage to provide domestic space heating. The results are promising, even for this basic system, and confirm that, with some modifications, such a system can provide adequate reliability. A significant result of this analysis has been to indicate the importance of selecting an appropriate value for the wind speed at which the wind turbine is to produce its peak output (the 'rated' wind speed). It is shown that the use of too high a rated speed not only greatly exaggerates the fluctuations in available power but could also result in a more expensive design of turbine for a given annual energy output.

Fig. 1 Histogram of the number of hours spent at different internal temperatures for a 17-yr period (149 × 10³ h).

For the main analysis a model system has been constructed in which electrically connected turbines at three typical well-spaced sites (Aberporth, Kinloss and Manston—three of the eight sites considered by Leicester *et al.*²) are used to provide the sole means of heating three groups of houses, one at each site. Each house is equipped with a thermal store having a half-power decay time of 150 h and the heat loss from the house is taken to be proportional to the difference between internal and external temperatures. (Although heat losses also depend to some extent on cooling by wind and rain, these effects are small and have not been included.) For this simple system the rate of supply of heat to the houses is determined by the natural heat loss from the store, although in a practical system some additional control is likely to be included; the houses themselves have a thermal time-constant of 10 h.

Each turbine has a power rating such that the total energy produced over the winter months (October–March) is just sufficient to maintain the houses at that site at a constant internal temperature of 20°C. Because in the short term wind power and heat losses (that is, external temperature) are uncorrelated, there will be some periods when insufficient power is available so that the house temperature will fall and, conversely, others when the supply of heat from the store is excessive and some has to be discarded. To simulate a national grid system the power from the three turbines is divided in such a way as to keep the internal temperatures of the three groups of houses equal and as close to the design value (20°C) as possible.

Table 1 Adopted turbine characteristics^{4,5}

Wind speed	
Rated wind speed	Relative power
0-0.5	0
0.6	0.2
0.75	0.5
0.9	0.8
1.0-2.0	1.0
>2.0	0

The results of this analysis are shown in Fig. 1 as a histogram of the number of hours spent at different internal temperatures. It is found that the temperature is within 3°C of the nominal value (that is >17°C) for 86% of the time and falls below 10°C for a total of only 462 h in 17 yr (0.3%). It is interesting to examine the results of our analysis for 1 February to 31 March 1975, a period considered as an 'extreme' example by Leicester *et al.*² The histogram for this period is shown in Fig. 2 (solid line) from which it can be seen that, even over this period, the temperature is above 16°C for over half of the time and never falls below 11°C. (Note that, with no change in the results, the system could also provide domestic hot water at a nominal temperature of, say, 60°C, with corresponding temperature fluctuations.) On the basis of these figures the reliability of the system would not seem to be very much worse than that of the conventional grid when the effects of miners' strikes, 3-day working weeks and so on are included.

The system considered here is extremely simple and possible enhancements which would undoubtedly improve the performance still further are: (1) the provision of a limited amount

Fig. 2 Histogram corresponding to Fig. 1 for the 'extreme period', February–March 1975 (Leicester *et al.*²) $V_R = 1.5 \bar{V}$ (solid line), $V_R = 2.3 \bar{V}$ (dotted line).

of non-degrading storage, for example, of the eutectic or chemical type which, in conjunction with the above system, would reduce the wastage of energy during warm periods. (2) The use of storage having the same capacity but better thermal insulation (as might be applicable to a small-scale district storage system) so that some control could be exercised over the rate at which heat was extracted. Avoiding the unnecessary heat loss at night, for example, would be important when considering the economics of the system.

We have used the measured performance figures of actual machines^{4,5} and, as described below, adopted a 'rated' wind speed of 1.5 times the mean wind speed, $\bar{V}$. By comparison, the generator characteristics used by Leicester *et al.*² are based on a higher rated wind speed and, also, give an output which seems to fall off unreasonably rapidly at the lower wind speeds. To show the effect of a higher rated speed we have recomputed the histogram of Fig. 2 for a rated speed of $2.3 \bar{V}$ (dotted line) from which it is apparent that the performance of the system is significantly degraded. In contrast to the results of Leicester *et al.*², who assumed an unrestricted rate of energy extraction from the store, in neither case is the store completely emptied over this period. The discrepancy between our results and those of Leicester *et al.*² can therefore be explained largely in terms of (1) the different wind-turbine characteristics which we have used

Fig. 3 Temporal distribution of combined power output from the three sites for two values of 'rated' wind speed; $V_R = 2.3 \bar{V}$ (solid line); $V_R = 1.5 \bar{V}$ (dotted line).

(Table 1) and (2) our use of a thermal store with an exponential decay. (However, it is not clear why the averaged heating demand as derived by Leicester *et al.*² should have such a low standard deviation (4.9%), a value which is remarkably small even allowing for a significant, and constant, demand for domestic hot water; in contrast, the weekly records of the energy used for heating our own laboratory between October 1977 and March 1978 show a s.d. of 30%.)

Finally, we discuss briefly the effect of variations in the rated wind speed of the turbine. ETSU⁶ have shown that for UK sites the maximum annual energy output is provided by a turbine having a rated wind speed approximately 2.3 times the mean wind speed, assuming that the cut-in speed, that is the speed below which no output is obtained, is about half the rated wind speed. However, such a turbine gives rise to prolonged gaps in the energy supply. If a lower rated wind speed is adopted these gaps are considerably reduced; conversely, if the rated speed is higher than $2.3 \bar{V}$, not only are the gaps seriously increased but the total energy output also falls. The effect of changes in the rated speed can be seen clearly in Fig. 3 which shows the number of hours for which a given combined output is obtained from the three sites considered previously. The histograms have been derived from two systems having the same total energy output

Table 2 Parameters of two wind turbines having the same annual output but different rated speeds

Parameters	$V_R = 2.3 \bar{V}$	$V_R = 1.5 \bar{V}$
Power rating	1 MW	300 kW
Rated wind speed	27 knots	18 knots
Diameter	46 m	52 m
Relative axial force	1.0	0.54
Relative torque	1.0	0.62
Estimated costs (£10 ³)		
Tower, foundations	22	17
Orientation	4	4
Rotor	30	34
Mechanical transmission	26	16
Alternator	12	5
Other items	14	14
Total cost	£108(000)	£90(000)

but with different rated speeds of 2.3 $\bar{V}$ (full line) and 1.5 $\bar{V}$ (dotted line). It is apparent that the former system has much longer periods of low or zero output and a correspondingly shorter time at which it is near its rated output.

Because, for a given swept area, reducing the rated speed from 2.3 $\bar{V}$ to 1.5 $\bar{V}$ decreases the annual energy output by ~20%, a proportionate increase has to be made to the size of the turbine blades to obtain the same mean output. The latter machine is, nevertheless, likely to be cheaper, because of the reduced ratings of the alternator and gearbox and the lower loading of the tower, as well as providing a more steady output. This is shown in Table 2 in which two designs having the same annual output are compared. The relative costs have been estimated using figures in the ETSU report⁶.

Our analysis has been concerned only with the time variations of available wind power in relation to fluctuations in the demand for space heating. Because of the normalisation carried out at the start of the analysis no knowledge of the absolute power demand is required and the results are independent of the type or number of houses to be supplied by the wind turbine or the precise temperature at which they are maintained. However, an approximate estimate of absolute energy requirements can readily be made. Assuming an average winter heating demand of 2 kW, a typical figure for a medium-sized, well-insulated house, a single turbine of the type considered in Table 2 would be sufficient to maintain about 90 houses at the temperature levels given in Fig. 1.

We thank the Meteorological Office for the supply of wind data. Financial assistance from the SRC to M.B.A. and from the Royal Commission for the Exhibition of 1851 to K.N. is acknowledged.

New materials in the
Si-C-Al-O-N and related systems

THE concurrent discovery at the Universities of Utah and Newcastle-upon-Tyne of a continuous series of solid solutions, with the 2H wurtzite-type structure, between silicon carbide (SiC) and aluminium nitride (AlN) is reported here. This, together with observations of the additional solubility of aluminium oxycarbide (Al₂OC), suggests a large extension to the already wide field of sialons. It offers the prospect of many more materials in the Si-C-Al-O-N and related systems that are of scientific and technological interest not only as engineering ceramics but also for their physical, chemical, and electrical properties.

Silicon nitride and silicon carbide are leading contenders for gas turbine and other high-temperature engineering applications. Extensive solid solution based on β -Si₃N₄ was first shown by Oyama¹ and by K.H.J. and Wilson² but only a few systems, such as Si₃N₄-Al₃O₃N, Si₃N₄-MgAl₂O₄ and Si₃N₄-

Fig. 1 X-ray photographs of 2H wurtzite-type solid solutions of SiC-AlN.

LiAl₅O₈, have been explored in detail. Investigation progressed in different directions³ when it was appreciated that the reversible replacement

is of general applicability and that the sialons are essentially aluminosilicates in which oxygen is partly replaced by nitrogen. A wide field of new materials exists, vitreous as well as crystalline, built up of (Si,Al)(O,N)₄ tetrahedra in the same way that the almost infinite variety of mineral silicates is based upon the (Si,Al)O₄ tetrahedron.

The formation of extensive solid solutions with silicon nitride and also with silicon carbide might seem surprising in that their covalent bonding, in addition to its high strength, is specific and selective. In the Si-Al-O-N system³ the extended homogeneity range of phases along lines of constant metal:nonmetal atom ratio M:X and the very restricted solubility in directions parallel to the AlN-SiO₂ join is due, at least in part, to the similarity of the two bond lengths

Si-N(1.75 Å) ~ Al-O(1.75 Å) (2)

and the difference between the other two bonds

Al-N(1.87 Å) ≠ Si-O(1.62 Å) (3)

The ready replacement of metal and nonmetal atoms in covalently bonded solids is not restricted, however, to that of Si-N by Al-O. Thus, a variety of polytypes M_mX_{m+1}, M_{m+1}X_m and MX with extended regions of homogeneity have been characterised recently⁴ in the Mg-Si-Al-O-N, Be-Si-Al-O-N and Al-C-O-N systems. Their structures are related to those of the silicon carbide polytypes and are based on the atomic arrangement of wurtzite.

Recent work at Newcastle⁵ has shown the existence of α' -sialons, that is, phases in the M-Si-Al-O-N system where M includes Li, Mg, Ca and Y, that are isostructural with α -Si₃N₄. The unit-cell contents are represented by M_x(Si,Al)₁₂(O,N)₁₆ where $x \geq 2$ and where the metal atoms M occupy partially or completely the only two interstitial sites in the structure. As

Table 1 Unit-cell dimensions of the end members of wurtzite-type solid solutions

	Dimensions (Å)	
	a	c
α -SiC(2H)	3.076	5.048
AlN	3.114	4.986
Al ₂ OC	3.19	5.09

shown by equations (4) and (5), the formation of α' -sialons from silicon nitride

is essentially by replacement of Si-N by Al-N and not by Al-O as in β' formation.

Although the preparation⁶ of wurtzite-type Al_3CON shows the possibility of producing carbon-containing sialons, the first attempts to do so at Newcastle were unsuccessful. Because diffusion coefficients in covalent solids are extremely small, solid solution is unlikely to be obtained by the heating and annealing of the powdered solid components; nor is it possible by melting. The other possibilities, by liquid-phase and vapour-phase reactions, have both now been used in preparing SiC-AlN solid solutions.

The preparation of silicon carbide and silicon nitride from silica by reduction with carbon or carbon plus nitrogen is a vapour-phase process⁷⁻⁹ involving the formation of SiO and CO. Similar reactions occur in the production of aluminium nitride from aluminium oxide (I.B.C., unpublished) and of sialons from clay¹⁰ and $\text{SiO}_2 : \text{Al}_2\text{O}_3$ gels (A. Hendry and K.H.J., unpublished). All such processes occur rapidly at relatively low temperatures, 1,400–1,600 °C. By using a very finely divided, high surface area, amorphous silica ('Cabosil') and a carbon source such as starch or sugar, an intimate and porous mixture of carbon and silica is produced by coking to remove all volatiles. Other oxides may then be homogeneously dispersed within the mixture by precipitation from their soluble salts. Using these techniques, with aluminium precipitated as hydroxide, reactions have been carried out at Utah in both argon and nitrogen atmospheres at 1,600 °C. These show 2H wurtzite-type solid solutions between SiC and AlN and between SiC and $\text{Al}_2\text{O}_3\text{C}$ extending in each case from 2m/o to 100m/o of the aluminium-containing component. In each case continuous shifts of reflections were observed in a single-phase wurtzite-type

Fig. 2 Unit-cell dimensions of 2H solid solutions of SiC-AlN.

diffraction pattern corresponding with the unit-cell dimensions for the end members given in Table 1.

At Newcastle it was considered that α' -sialons were obtained by reaction of Si_3N_4 with AlN plus relatively small concentrations of CaO or Ca_3N_2 because of the formation of a liquid phase in which the reactants have some solubility. When α' - $\text{CaSi}_2\text{Al}_3\text{ON}_{15}$ was reduced in a carbon crucible at 1,800 °C for 30 min in flowing nitrogen the product was single phase with a wurtzite-type structure of unit-cell dimensions corresponding to 3SiC. AlN. No calcium was detected in the product and in the same experimental conditions calcium oxide was completely reduced and volatilised as calcium vapour and carbon monoxide. In subsequent experiments at the same temperature, mixtures of Si_3N_4 , AlN and CaO were reacted with carbon instead of using the preformed α' -sialon. It is thought that the addition of CaO provides a transient oxynitride liquid in which the reactants are soluble.

Fig. 3 Linear coefficients of expansion (20–1,000 °C) of solid solutions of SiC-AlN.

SiC-AlN solid solutions were also obtained at Newcastle by heating intimate mixtures in molecular nitrogen at 1,400–1,500 °C of SiO_2 , Al_2O_3 and C obtained by a sol-gel process. The products always contained some β -SiC, unlike those prepared by essentially the same process at Utah. The formation of β -SiC depends on impurities, and also on nitrogen pressure, but it is clear from the present results that β , once formed, does not readily react with AlN to give a solid solution.

Figure 1 shows X-ray photographs of 2H solid solutions of 3AlN:SiC, AlN:SiC and AlN:3SiC compared with that of pure AlN. The shifts of X-ray reflections show that c increases and a decreases as AlN is replaced by SiC. This variation in cell dimensions is shown by Fig. 2. The mean coefficients of expansion α_a and α_c at 20–1,000 °C for the composition AlN:SiC are compared with values for the end members in Fig. 3. The value of about 5×10^{-6} per °C is probably too high for the use of the material in gas turbine applications but the electrical and semi-conducting properties are expected to be of interest.

As extensive solubility between the end members of the SiC-AlN solid solution occurs with $\text{Al}_2\text{O}_3\text{C}$, five component Si-C-Al-O-N phases must occur although their ranges of homogeneity have not yet been established. Moreover, there are many nitrides, oxynitrides and carbo-oxynitrides with wurtzite-type structures, for example LiSi_2N_3 , MgSiN_2 , LiSiON , MgSiAlN_3 and Al_3CON , and so in appropriate conditions these should also form solid solutions with SiC-AlN.

The new materials based on Si-C-Al-O-N in combination with a variety of network-modifying metals will not all be useful ceramics but their other properties are worth investigation. Moreover, they provide a new and hitherto unexplored area of inorganic chemistry.

New isotopic evidence for the origin of Red Sea brines

THE hot brines in the Atlantis II Deep in the Red Sea (Fig. 1) have concentrations of both oxygen- and hydrogen-isotopes which are different from those of the overlying Red Sea deep water but are identical to the surface waters, only at the southern parts of the Red Sea^{1,2}. It was inferred, therefore, that these brines originated in the southern Red Sea and have migrated northwards to their present location. This hypothesis has often been questioned, using mainly geological arguments, the most striking of which is the improbability of a plumbing system which had to work over a distance of more than 800 km (refs 3, 4). However, the geochemical problem of the depletion in heavy isotopes in the hot brines as compared to the directly overlying seawater has still not been solved. We can add new data to this discussion from stable isotope analyses carried out on new brines which were found throughout the Red Sea (Fig. 1). Many of these occurrences are between the Atlantis II Deep and the southern Red Sea⁵.

Our analytical procedures were the same as those for the early isotope analyses on the Atlantis II Deep brines¹ and are described in detail elsewhere^{6,13}. The accuracies were $\pm 0.07\%$ and $\pm 0.5\%$ for oxygen and hydrogen, respectively.

The results are given in Table 1 and Fig. 2. Many of the brines have chlorinities which are appreciably lower than the nearly saturated brine in the Atlantis II Deep. We assume that this is due to dilution by seawater after intrusion of the saturated brines. This would have caused a change in the isotopic compositions if seawater and brines differed in their initial isotope content. Therefore, we calculated the assumed compositions of the brines before their dilution. These 'corrected' values are shown in Table 1 and Fig. 2.

The brines exhibit a considerable variation in their isotopic content. However, those brines near the Atlantis II Deep are isotopically identical. These include the Atlantis II Deep itself, the Discovery Deep, the Chain Deeps and the Albatross Deep (Fig. 1). This homogeneity supports previous assumptions^{5,7} that the brines in the Atlantis II Deep area are from one source and

Fig. 1 Locations of Atlantis II Deep brine pools and of new brine occurrences in the Red Sea^{5,19}.

probably have subsurface connection. The presence of nearly identical brines in the Albatross Deep is now understood better and could not be explained by the overspill theory⁸.

The Valdivia Deep is an elevated position located away from the central rift 10 km west of the Atlantis II Deep system (Fig. 1). Its brines have significantly higher D/H and $^{18}\text{O}/^{16}\text{O}$ ratios than the Atlantis II Deep brines. They are the only example of brines which are isotopically identical to present-day Red Sea water, which suggests that they originated from present-day Red Sea deep water, or from Red Sea palaeowaters of present-day composition. For this brine pool, a dissolution of exposed evaporites⁹ by present day Red Sea deep waters is likely.

The brines from the Erba, Port Sudan and Nereus Deeps are enriched in both D and ^{18}O and exceed the range of present-day Red Sea deep waters. Only a few processes could have caused a simultaneous enrichment of D and ^{18}O as shown in Fig. 2 for these three brines. An enrichment by evaporation is highly unlikely as these brines have never been exposed to air. Mixing of recent Red Sea water with only one subsurface brine having a specific isotopic composition is excluded as the adjustment of these values to brines unmixing with seawater (corrected values in Table 1) should then result in identical isotopic compositions, and the corrected values differ significantly. The δD and $\delta^{18}\text{O}$ values of the three brines under discussion fall nearly on a line in the $\delta\text{D}/\delta^{18}\text{O}$ diagram; this line is located between present-day Red Sea deep water and Red Sea deep water of the last glacial maximum 18,000 yr BP (III in Fig. 2). This value was estimated using ^{18}O -variations in foraminifera in Red Sea sediments which are given in Fig. 3. The total ^{18}O -enrichment, $\Delta^{18}\text{O}$, during the last glacial maximum was $\sim +2\%$ in ^{18}O as compared with present-day values. The $\Delta^{18}\text{O}$ values in Fig. 3 are the approximate ^{18}O -oscillations of the Red Sea waters during the past 20,000 yr as surface water temperatures did not change significantly during this period¹⁰. The Red Sea deep water-values given in Fig. 2 have been estimated with the assumption that the $\delta^{18}\text{O}/\delta\text{D}$ relationship of Red Sea deep water relative to open ocean water (SMOW) (that is $\delta\text{D} = 6\delta^{18}\text{O}$ (ref. 1)) has prevailed.

Table 1 $^{18}\text{O}/^{16}\text{O}$, D/H-isotope and chloride data for waters of various brines in the Red Sea

Location	Cl (gper kg)	$\delta^{18}\text{O}^*$ (‰)	δD^* (‰)	$\delta^{18}\text{O}^\dagger$ (‰)	$\delta\text{D}^\dagger$ (‰)
Atlantis II Deep	+156.0	+1.21	+7.4	+1.19	+7.3
Chain A-Deep	+154.8	+1.29	+8.2	+1.26	+8.0
Chain B-Deep	+155.5	+1.19	+7.5	+1.16	+7.3
Chain C-Deep	+154.2	+1.22	+7.5	+1.19	+7.3
Discovery Deep	+155.1	+1.16	+7.5	+1.13	+7.3
Albatross Deep	+143.5	+1.20	+7.7	+1.10	+7.2
Valdivia Deep	+144.6	+1.84	+11.5	+1.83	+11.5
Erba-Deep	+83.8	+1.98	+13.0	+2.09	+14.9
Port Sudan-Deep	+124.8	+2.39	+15.0	+2.57	+16.2
Nereus-Deep	+129.5	+2.64	+17.2	+2.86	+18.9
Kebrit-Deep	+153.2	+1.05	+10.4	+1.00	+10.3
Suakin-Deep	+85.8	+2.56	+21.6	+3.35	+33.6

δ -values are reported versus SMOW and are defined as

$$\delta = \frac{R_{\text{sample}} - R_{\text{standard}}}{R_{\text{standard}}} \times 1,000 (\text{‰})$$

where R is the D/H and the $^{18}\text{O}/^{16}\text{O}$ ratio respectively.

* Measured values. The original brines are supposed to be diluted by Red Sea Water so the corrected data for undiluted brines are calculated according to the following formula:

$$\delta_{\text{corr}} = (\delta_{\text{Brine}} - x_1 \delta_{\text{SW}}) / (1 - x_1)$$

δ_{Brine} are the measured isotope data*, δ_{SW} the data of recent Red Sea deep water ($\delta^{18}\text{O}_{\text{SW}} = 1.89\text{‰}$, $\delta\text{D}_{\text{SW}} = 11.5\text{‰}$ (ref. 6)). The sea water contributions x_1 to the actual brines are calculated from the respective contents $\text{Cl}^-_{\text{Brine}}$: $x_1 = (\text{Cl}^-_{\text{Brine}} - 160.8) / (22.5 - 160.8)$. The saturation Cl^- -concentration of Atlantis II brine is 160.8 g per kg at 25 °C (ref. 2); 22.5 g per kg (ref. 6) was determined for recent Red Sea deep water

We conclude that the brines from below the Erba, Port Sudan and Nereus Deep are Red Sea waters, which infiltrated to sub-bottom strata during times when the isotopic composition of the Red Sea was significantly enriched in heavy isotopes as compared with today; that is, these brines are essentially derived from Red Sea palaeowaters.

The same concept could also explain the origin of the Atlantis II Deep brines. During past pluvial periods the Red Sea water was depleted in ^{18}O by up to 1‰ compared to open ocean water¹¹. An ^{18}O -depletion is also indicated in Fig. 3 by the negative $\Delta^{18}\text{O}$ values at inferred ages that are about 5,000 yr BP. We therefore propose that the isotopic composition of the Atlantis II Deep should not be related to present-day Red Sea surface waters but more likely to isotopically depleted Red Sea deep waters from previous pluvial periods. The depletion in ^{18}O of $\sim -0.5\%$ during the last climatic optimum ($\sim 5,000$ – $8,000$ yr BP) as indicated in Fig. 3 is sufficient to explain the isotopic composition of the Atlantis II Deep brines which are also depleted by 0.6‰ as compared to present day Red Sea deep waters.

The concept of a palaeowater origin of the brines in the Red Sea agrees with the widespread occurrence of brines and eliminates the need to hypothesise their derivation from waters to the far south. We assume that these palaeowaters were trapped in an earlier geological period and have been stored since then in subterranean strata. Alternatively, dynamic systems have to be assumed where the subsurface flow times of these systems are of the order of 7,000–15,000 yr.

The brines in the Kebrit and Suakin Deepes do not have isotopic compositions within the range of possible Red Sea palaeowater compositions. Some specific waters of the meteoric water cycle have similar compositions. Such waters were found in lakes in the Danakil Desert¹² or in hot springs in the area around Djibouti¹³. The intrusion of such waters at the bottom of the Red Sea is unrealistic. Therefore, we assume the Kebrit and Suakin brines to be Red Sea palaeowaters which have changed their isotopic compositions due to secondary effects. High temperature exchange reactions between minerals and waters

Fig. 2 Isotopic composition of Red Sea brines and some inferred source fluids. Each brine which has a salinity higher than the Atlantis II Deep brine has a corrected value (○) which is connected with the measured value (●). The corrected values give the original isotopic composition of the brines, if it is assumed that the lower salinities were caused by dilution with present-day seawater. The isotopic variation of world ocean water and Red Sea deep water is shown for the following stages: I interglacial (last climatic optimum 8,000–5,000 yr BP), II present day and III glacial maximum 18,000 yr BP. The isotopic composition of interstitial waters is not well defined (J. R. Lawrence, personal communication); the indicated field encloses the reported analytical uncertainties¹⁶.

Fig. 3 Variation of the ^{18}O concentration in the Red Sea during the past 20,000 yr. The $\Delta^{18}\text{O}$ values are defined as $\delta^{18}\text{O}_{\text{present}} - \delta^{18}\text{O}_{\text{reconstruct}}$ and show the relative change of ^{18}O in foraminifera in the Red Sea as compared to present day foraminifera values. As the temperature variations in the Red Sea waters were small, the $\Delta^{18}\text{O}$ values represent approximately the variations in ^{18}O in sea water. The time scale has been inferred by assuming the time of maximum ^{18}O enrichment to be 18,000 Yr BP. The ^{18}O concentrations of the brines are given for comparison and are also plotted as differences from present day Red Sea deep water. This comparison shows that the variations in ^{18}O in seawater cover those in the brines.

are improbable. Even the Atlantis II Deep brines, which exhibit the highest temperatures, do not show any ^{18}O isotope shift². We suggest, however, that low temperature mineral reactions, similar to those which alter pore fluid compositions^{14,15} should be considered. Interstitial waters in the Red Sea sediments have been analysed in bore holes near the brine deepes (GC 225 and GC 228 in Fig. 1). Although the ^{18}O concentrations in these fluids could be determined only with great uncertainty (J. R. Lawrence, personal communication), it is important to our results that interstitial waters are similar in their isotopic compositions to those brines which do not fit to proposed unaltered palaeowaters. These waters also tend to be different as compared to Red Sea deep waters and Red Sea palaeowaters and are similar to the brines at the Suakin and Kebrit Deepes. The brines of the Kebrit and Suakin Deep may, therefore, be interpreted as accumulations of expelled interstitial waters.

This interpretation is somewhat speculative, especially taking into account the isotopic composition of the Suakin brines before dilution. However, alternative source fluids like downwards migrated meteoric waters from the Saudi Arabian coast³ are even more speculative and formation waters¹⁸ are ruled out by their isotopic composition.

Texture discrimination and Fourier analysis in human vision

NEUROPHYSIOLOGICAL experiments have shown that many cells in the visual cortex of the cat and monkey respond well only if the retinal image contains a line stimulus of appropriate orientation and width (spatial frequency)^{1,2}. Different cells are sensitive to different orientation/spatial frequency combinations and judging from numerous corroborative psychophysical experiments, it seems highly probable that similar populations of cells exist in man also³. However, the function of these cells is not known. One suggestion is that they decompose the retinal image into its two-dimensional Fourier components and that processes such as object recognition, region finding and image segmentation then operate on this Fourier description^{4–7}. We report here experimental results on human texture discrimination which argue against this possibility by showing that textures which differ markedly in their Fourier spectrum are not always readily discriminable.

Figure 1 illustrates the texture discrimination task we used. Each stimulus had one 'target' quadrant whose texture differed from that used for the other three quadrants. The stimuli were presented in a tachistoscope and latencies were measured for discrimination of the target. A buzzer warned the subject when a stimulus was about to appear and he indicated his choice for target quadrant by pressing one of four response keys, arranged in a panel to match the layout of the stimulus quadrants. His response terminated the stimulus presentation and also stopped a timer which recorded response latency. Each stimulus was presented four times during an experimental session lasting about 30 min. The location of the target quadrant was varied randomly from trial to trial except that each quadrant was used once for the target for each stimulus. Stimuli were presented in a different quasi-random order for each subject which ensured that he did not know which quadrant was to be the target on any given trial.

Textures consisted of either one sinusoidal grating (45°, Fig. 1a and d), two sinusoidal gratings added together (45° + 105°: Fig. 1b and e), or three sinusoidal gratings added together (45° + 105° + 165°: Fig. 1c and f). In half the stimuli the target quadrant differed from the other quadrants in the spatial frequency of its texture (2.2 and 4.4 cycles per degree respectively: Fig. 1a–c). In the other half the target differed in the orientation of its components (30° rotation: Fig. 1d–f). All stimuli were generated by computer and produced as hardcopy on a full-tone facsimile picture recorder (Muirhead type K-550-B/1).

The reader is invited to judge for himself the difficulty of finding the target quadrant in each of the stimuli shown in Fig. 1. Subjects made the various spatial frequency discriminations very quickly but took much longer over the orientation ones. Even the quickest orientation case (Fig. 1d) produced a mean latency twice as long as any of the spatial frequency ones and in the three-component orientation condition (Fig. 1f) the latency is extremely long indeed.

We have also studied this kind of texture discrimination task using 200-ms tachistoscopic stimulus presentations which prevent benefit from scanning eye movements. Texture discriminations which can be made in such circumstances are

sometimes called 'immediate' to distinguish them from discriminations requiring much more lengthy and careful scrutiny⁸. The spatial frequency discriminations remained easy using 200 ms presentations whereas the orientated type could not be performed reliably, even in the one-component condition⁹. We have also found that these conclusions apply to textures composed of filtered random noise (which appear like woven fabrics).

These results are difficult to reconcile with any theory in which it is assumed that the processes of texture discrimination have immediate access to information corresponding to a local piecewise Fourier analysis. In Fourier terms, the difference between target and non-target textures in all the stimuli of Fig. 1 is clearcut, consisting as they do of widely separated pure sinusoids. Given a Fourier model, therefore, easy discrimination would be expected in all cases but this was not the obtained result.

The results are also difficult to reconcile with Julesz's theory of texture vision¹⁰. Julesz has proposed that textures which differ only in their 3rd or higher order statistics cannot be discriminated without scrutiny. This conjecture does not entail, of course, that all textures differing in their lower order statistics be discriminable. Even so, the second order differences between target and non-target quadrants in Fig. 1 are marked and this makes the relative difficulty with orientated discriminations surprising, given Julesz's basic thesis.

An alternative theory of texture vision has been formulated by Marr¹¹ in which the processes of texture vision have access to a rich but primitive symbolic description of the visual scene called the 'primal sketch'. According to Marr's theory, the primal sketch is computed from local measurements taken at every position in the visual image by the orientated spatial frequency channels. The outputs of these channels are then used to produce a description of the kind of edge or blob present at

Fig. 1 Sample stimuli used in the experiment. Times alongside each figure are group mean latencies ($n = 9$) for detection of the target quadrant (s.e.m. in brackets).

each location, with channel outputs not available to subsequent processes. Consider, for example, Fig. 1c. In terms of Marr's theory, the measurements taken by the various orientated channels are used to form 'assertions', entered into the primal sketch, about the presence of blobs of a particular size and contrast. The clear cut differences in orientated spatial frequency channel activity which would be generated are of no relevance to subsequent processes. Instead, in order to detect the odd quadrant higher-order grouping processes are required to aggregate the blobs into rows. It is only after this grouping process (which would be maximally difficult in Fig. 1f—hence the longest latency for this condition) that the orientation differences in the textures can be detected. On the other hand, in the case of a discrimination based on spatial frequency differences, no such processing is required as the size of the blobs is written directly into the primal sketch and is thus available directly to the processes of immediate texture discrimination. Clearly, our results are compatible with Marr's ideas and challenge any theory which suggests that the outputs of orientated spatial frequency channels are used directly for immediate texture vision.

Artificial menstrual cycles, behaviour and the role of androgens in female rhesus monkeys

THE sexual behaviour of higher primates has special relevance to the human situation. The rhesus monkey, for instance, has a true menstruation, and copulation occurs throughout the cycle. Levels of sexual activity, however, are generally higher in the peri-ovulatory period¹, and a similar mid-cycle maximum has been reported for certain human couples². Androgens increase the sexual behaviour of rhesus females^{3,4}, and they have been used to treat loss of libido in women⁵. These observations, together with the rise in plasma testosterone near mid-cycle, have led to suggestions that androgens may be the main libidinal hormone in the female⁶. We report here our experiments to test this hypothesis. We devised a daily dose schedule of oestradiol, testosterone and progesterone for ovariectomised rhesus monkeys that duplicated the changing plasma levels during normal menstrual cycles. When males were paired with females so treated, sexual activity showed a pattern similar to that during the normal cycle, and the omission of testosterone was without any detectable effect on this pattern.

Oestrogens given in physiological amounts to ovariectomised female rhesus monkeys increase the sexual behaviour of the pair, whereas injections of progestins antagonise the effects of oestrogen⁷. Testosterone given in pharmacological amounts to ovariectomised females both increases female sexual invitational behaviour⁸ and increases their lever-pressing for access to a male partner in an operant situation⁹. This has raised the question of whether the physiological increase in testosterone,

Fig. 1 Doses of oestradiol benzoate (upper histograms) and progesterone (lower histograms) given daily by subcutaneous injection to eight ovariectomised rhesus monkeys to imitate the changing plasma levels during normal cycles. Mean levels of oestradiol (upper graph) and progesterone (lower graph) in plasma samples drawn 8 h after injections during 24 artificial menstrual cycles (●) are compared with mean plasma levels for five intact females during 33 normal menstrual cycles (○). Each point represents the mean of 7–32 values. Vertical bars given standard errors of the means.

rather than the increase in oestrogen levels, near the middle part of the menstrual cycle may be primarily responsible for the menstrual rhythms in sexual behaviour.

Eight female and eight male rhesus monkeys were used in this study. The females were ovariectomised 3 months before the start of the experiment. Doses of oestradiol benzoate, progesterone and testosterone propionate in 0.2 ml sesame oil were administered subcutaneously at 08.00 h each morning according to the 28-d dose schedule shown in Figs 1 and 2. Females so treated had a normal menstruation every 28 d, and we have called these cycles 'artificial menstrual cycles'. Blood samples were collected at 16.00 h three or five times per week, and were analysed for oestradiol, progesterone and testosterone simultaneously using a radioimmunoassay involving chromatography on Sephadex LH20. Changes in the plasma levels of these steroids in 24 artificial menstrual cycles were closely similar to the levels in 33 normal cycles (Figs 1 and 2). Mean values were within the inter-individual variation for this species. When testosterone propionate was omitted from the daily dose schedule (eight cycles), plasma testosterone levels were steady throughout (adrenal secretion) and were similar to the levels in females receiving control injections of vehicle only (Fig. 2b). Thus, the administration of physiological doses of oestradiol and progesterone was without any detectable effect on the secretion of testosterone by the adrenals.

To determine the effect of these dose schedule on sexual behaviour, each female was paired alternately with one of two male partners (groups 1 and 2). Behaviour tests of 1-h duration were observed from behind one-way vision mirrors, and scores were entered directly into a computer through terminals in the observation booths. The number of ejaculations per test is used here as a measure of the males' sexual activity. To measure the females' motivation for propinquity with males, four of the females (eight pairs) were tested in an operant situation that permitted them to press a lever 250 times to gain access to a male partner. The females were allowed 30 min to perform this task and a 1-h behaviour test followed, either immediately, if access was attained, or later the same day, if it was not⁹.

When males were paired with females with artificial menstrual cycles, sexual activity showed a very consistent pattern similar to

440

that of the normal cycle. Ejaculatory and operant performance were significantly higher during oestradiol, progesterone and testosterone cycles than during control cycles. Ejaculations increased from 0.90 $\pm$ 0.05 per test ($n = 479$) in control cycles to 1.31 $\pm$ 0.04 per test ($n = 447$) in artificial cycles. The mean access time was 573.1 $\pm$ 55.1 s ($n = 80$) in control cycles and 515.6 $\pm$ 23.6 s ($n = 443$) in artificial cycles. The frequency of ejaculations (0.94 $\pm$ 0.05 per test) was significantly higher in artificial cycles than in control cycles (0.90 $\pm$ 0.05 per test). The mean access time (573.1 $\pm$ 55.1 s) was significantly higher in control cycles than in artificial cycles (515.6 $\pm$ 23.6 s). The frequency of female sexual invitations (presentations, hand-reaches, head-ducks and head-bobs) was significantly higher in artificial cycles than in control cycles. The mean male success ratio (percentage of male mounting attempts not refused by the female) was significantly higher in artificial cycles than in control cycles. The mean male success ratio was 90.5 $\pm$ 2.7% ($n = 65$) in control cycles and 94.5 $\pm$ 2.7% ($n = 443$) in artificial cycles.

Figure 3 shows changes in ejaculations, access times, female sexual invitations (presentations, hand-reaches, head-ducks and head-bobs) and in male success ratios (percentage of male mounting attempts not refused by the female) during these artificial cycles. Cyclic patterns of ejaculation occurred in all 24 cycles when all three steroids were administered and in all eight cycles when testosterone was omitted; there were no significant differences (analysis of variance) between cycles with and without testosterone. Access times were shortest in the week of highest oestradiol dosage in both types of artificial cycle. There were no consistent changes either in female proceptivity as measured by sexual invitations or in receptivity as measured by male success ratios, and there was clearly no evidence for reduced numbers of invitations or decreased male success ratios in cycles without testosterone.

These results are consistent with those of others¹⁰ in suggesting that the mid-cycle increase in plasma testosterone during normal menstrual cycles is of ovarian rather than of adrenal origin. Although functional adrenal glands (a major source of androgen in females) are necessary for the expression of many patterns of behaviour, including those of sexual behaviour¹¹, it seems unlikely that the physiological mid-cycle surge in testosterone plays any significant part in the increase in female sexual motivation at this time. The changes in behaviour observed in

Fig. 2 a, Daily doses of testosterone propionate given by subcutaneous injection (histograms) used in artificial menstrual cycles, and mean plasma levels of testosterone in 24 artificial cycles (●) compared with 33 normal cycles (○). b, Mean plasma levels of testosterone in eight artificial cycles (eight females) during which the schedule of oestradiol and progesterone was continued but in which testosterone propionate was omitted. The horizontal interrupted line represents the mean testosterone level (127.6 $\pm$ 25.7 pg per ml, $n = 45$) during control cycles when vehicle only was injected. Vertical bars give the s.e.m.

Fig. 3 Changes (means per test) in ejaculations, access times, female invitations and male success ratios during artificial menstrual cycles with oestradiol, progesterone and testosterone (●) and with oestradiol and progesterone alone (○) (2-d running means). Each point represents the mean of 8-48 tests. Black squares indicate menstruation.

the earlier studies cited were produced by doses (0.5-1.0 mg testosterone propionate) that were 15-400 times those used here (2.5-30.0 μ g). These pharmacological doses produce plasma levels in the female rhesus monkey that are well within the normal range for males (4.0-25.0 ng per ml) rather than within the physiological range for females (100-800 pg per ml) that were obtained here. On the other hand, these studies show that normal behaviour cycles result from artificial cycles of physiological doses of oestradiol and progesterone. These findings support the view that the mid-cycle increase in oestradiol is sufficient to account for the increase in sexual activity during the peri-ovulatory period of the normal menstrual cycle.

Elaborate CNS cooling structures in large dinosaurs

DURING sustained activity, or when exposed to high ambient temperatures, terrestrial animals often experience periods of core hyperthermia. The central nervous system (CNS) is very sensitive to elevated temperatures¹⁻³, and consequently, both bradymetabolic and tachymetabolic⁴ terrestrial vertebrates have evolved physiological mechanisms which effect localised cooling of the brain, and thereby reduce any thermal impairment of CNS functioning. In modern reptiles this temperature gradient is produced by evaporative cooling from the buccal cavity and upper respiratory tract^{5,6}, conducting heat from the brain through the floor of the cranium⁷. Mammals dissipate heat, by evaporation, from the nasal mucosa to the air flowing through the nasal passages. The cooled venous blood draining from this highly vascularised mucosa flows into the cavernous sinus, where counter-current heat exchange with the carotid arteries, elaborated into a rete in many forms, results in brain cooling^{8,9} (Fig. 1a). Dinosaurs would have experienced similar thermal problems to those of modern vertebrates, and these would have been particularly acute in the larger forms whose low surface area to volume ratio would have restricted dissipation of the enormous amounts of heat generated by the skeletal muscles during activity. It is therefore proposed that they required and possessed comparable physiological mechanisms to protect the brain during core hyperthermia.

In the lambeosaurine hadrosaurs, air entering the nostrils passed through extensive passages in a crest formed by the premaxillae and nasal bones before descending the choanal tube to the throat (Fig. 2a). Early workers associated the function of these crests with a semi-aquatic mode of life. The theories proposed included air storage chambers or traps to prevent water entering the lungs¹⁰, but evidence now indicates that hadrosaurs were predominantly terrestrial^{11,12}. Ostrom^{13,14} showed the early theories to be untenable and concluded that the function of the crests was to increase the area of mucosal

Fig. 1 a, Schematic diagram of the blood vessels involved in brain cooling in the sheep (after Hayward and Baker⁹). b, Proposed mechanism of brain cooling in *Edmontosaurus*. Cooled venous blood from the nasal capsule drains into the enlarged orbital sinuses where it conducts heat from the brain.

Fig. 2 a, Section through the narial crest of the hadrosaur *Lambeosaurus* illustrating the expanded nasal passages and their position relative to the brain (black). EN, external naris; NC, nasal capsule; O, orbit (after Ostrom¹⁴). b, Skull of the hadrosaurine *Edmontosaurus* showing probable position of the cartilaginous nasal capsule (after Ostrom¹⁴). c, Enlargement of the orbit and postorbital pouches (P) of *Edmontosaurus* (after Ostrom¹³).

epithelium lining the nasal passages, suggesting that this enlargement was for enhanced olfaction. However, it seems likely that the function was primarily thermoregulatory. Although probably too small to have an appreciable effect on core temperature, the enlarged mucosal area would have increased the rate of evaporative heat loss from the head and hence prevented excessive elevation of brain temperature. This idea is supported by the proximity of the passages to the cranium, which would have been cooled by direct conduction into the crest and by the action of the cooled venous blood draining from the mucosa. As in modern mammals, the rate of cooling may have been related to the regulation of air flow through the nasal passages, with panting occurring during heat stress¹⁵. This proposal is not incompatible with the suggestion^{16,17} that these crests, and those of the saurolophine hadrosaurs, also functioned in visual display.

The non-lambeosaurine hadrosaurs lacked hollow narial crests, but their external nares were conspicuously expanded and probably contained an enlarged cartilaginous nasal capsule¹⁴ (Fig. 2b), the lining of the channels within which would have formed an extensive evaporative surface. Unlike the lambeosaurine crests, the location of this surface indicates little influence on brain temperature by direct heat conduction; however, the venous blood draining from it would have cooled the cranium. Evidence for this is the presence, in some genera, of large pouch-like cavities in the postorbital bones (Fig. 2c). Ostrom¹³ suggested these resulted from enlargement of the orbital sinuses, venous structures which in modern reptiles collect blood from the surrounding areas of the head and empty into the internal jugular veins. If this interpretation is correct the cooled venous blood from the nasal capsule would have drained

into these enlarged sinuses, the proximity of which to the cranium would have resulted in brain cooling (Fig. 1b). Furthermore, counter-current heat exchange may have occurred between the jugular venous and carotid arterial blood, similar to that described in modern mammals⁸ and reptiles¹⁸.

Many sauropods greatly exceeded 10 tonnes in weight and were the largest known dinosaurs. The external nares of these animals were situated high on the skull and were usually very large, indicating a spacious nasal capsule (Fig. 3). This location of the nares was thought to have been an aquatic adaptation, allowing these animals to breathe while almost totally submerged¹⁰; but the nares of most aquatic reptiles are small, unlike those of sauropods. From the structure of the vertebral column and limbs, Bakker^{19,20} proposed that sauropods were terrestrial although he was unable to clarify the functional significance of the dorsal position of the nares. However, both the size and location of the nasal capsule are consistent with its having an important role in brain thermoregulation, its enlargement increasing the mucosal area available for evaporation and its position reducing the distance between this cooling surface and the cranium. The long neck of these dinosaurs increased the thermal isolation of the head from the body and extended the distance available for heat exchange between the jugular veins and carotid arteries. This explanation of narial structure strongly supports the evidence that sauropods were terrestrial¹⁹⁻²¹ and argues against the aquatic theory.

As in sauropods, hadrosaurs and large ornithomimid dinosaurs such as *Iguanodon*, the nasal region of the skull of the ceratopsians was greatly enlarged and again the nasal mucosa was probably the main site of heat dissipation. In modern ruminants²² the surface of the bony horn cores is covered with a rich vascular plexus which vasodilates during heat stress, resulting in increased blood flow through the horns. This blood, cooled by convection and radiation from the surface of the horns, drains into the cavernous sinus where it comes into contact with the carotid rete and cools the arterial blood entering the brain. Most ceratopsians possessed one or more horns with cores very like those of ruminants¹⁰. A network of channels on their surface indicates that they too were highly vascularised and therefore could have functioned comparably in brain thermoregulation. Vascularisation of the surface of the ceratopsian

parietal-squamosal neck frills, especially the marginal areas not overlain by jaw musculature²³, would also have permitted additional heat loss from the head.

In the carnosaurs, whose external nares are not as enlarged as those of other large dinosaurs, a major site of heat loss was probably, as in modern reptiles, the lining of their enormous buccal cavity. In some forms there was considerable flexibility between the various jaw elements, structural modifications thought to have facilitated the engulfing of large portions of prey¹⁰. This could indicate the presence of a fairly extensive gular area which would have also further extended the evaporative surface area. Additional cooling may have been achieved by active pumping or fluttering of this gular region, a method used by large varanid lizards²⁴ and birds such as the ostrich²⁵.

Some large dinosaurs evolved structures which can be interpreted as providing thermal protection for the extracranial CNS. The vertebrae of many forms contain deep excavations which probably contained an air sac system similar to that of birds²⁶. Ventilation of this system would have removed heat from the region around the spinal cord. Not surprisingly, the excavations are particularly extensive in the vertebrae of sauropods²¹, which, because of their size, would have been especially vulnerable to hyperthermia. *Stegosaurus* possessed additional radiative and convective structures consisting of a double row of bony plates, well permeated by blood vessels, running along the neck, back and tail²⁷. Although the size of these plates suggests they significantly influenced core temperature, the spinal cord would have been particularly well protected from elevated temperatures by the cooled blood draining from the plates directly above it. The largest plates are located in the sacral region where the spinal cord was apparently enlarged into a ganglion exceeding the brain in size. The vertebral neural spines of a few dinosaurs, such as *Spinosaurus* and *Ouranosaurus*, were extremely elongated and are thought to have supported a vascular sail-like structure which would similarly have permitted increased radiative and convection heat loss, so cooling the spinal region.

The described CNS cooling mechanisms do not constitute direct evidence that dinosaurs were either bradymetabolic or tachymetabolic animals, as such physiological mechanisms are found in the extant groups of both. However, the apparent very highly developed nature of these structures in dinosaurs does tend to support the idea that they may have been tachymetabolic, with a high metabolic level and resulting endogenous heat production, rather than bradymetabolic like modern reptiles. Unfortunately, the nervous and vascular systems are not preserved in fossils and it is only possible to observe the structure of those portions which leave an impression on the skeleton. This makes it impossible to establish the detailed physiological functioning of the proposed cooling mechanisms, but it seems reasonable to assume that they would have been as sophisticated as those of modern vertebrates, incorporating heat-exchanging retes and vascular shunts^{18,28} allowing control of blood flow to and from the cooling surfaces.

I thank Dr K. Bowler for discussions, and Professor J. E. Heath and Dr T. S. Kemp for critical reading of the manuscript.

Unusual response of DDT-resistant houseflies to carbinol analogues of DDT

THE toxic action of DDT is thought to be caused by complex formation between the insecticide and nerve protein, a mechanism consistent with the well known phenomenon of negative correlation between insect mortality and temperature¹. We present here evidence which indicates that some carbinols which are close analogues of DDT may have a different mode of action. These compounds elicit very different symptoms of poisoning, and none of the major mechanisms of resistance to DDT in the housefly confers significant resistance to these compounds.

Several analogues of DDT (Table 1) were tested against strains of houseflies (*Musca domestica* L.) with known genetically isolated mechanisms of resistance to DDT. These strains were: Beiruth (heterozygous for *DDTase*), 2778 (*DDT md*, monooxygenase, sesamex-suppressible resistance), 538 ge (*kdr*-resistance)² and Super-*kdr* (*kdr*-like resistance). This last mechanism, not yet fully characterised, was recently isolated from the multi-resistant 153y3 strain of houseflies by the chromosome isolation technique³. Super-*kdr* resembles *kdr* in many respects; it is controlled by one or more incompletely recessive factor(s) on chromosome 3, confers resistance not only to DDT and its analogues but also to the pyrethroids, and is unaffected by pretreatment with FDMC (bis(*p*-chlorophenyl)trifluoromethyl carbinol; 1 µg per fly), piperonyl butoxide (2 µg per fly) or the two additives applied together. Also, it crosses freely with *bwb* (brown body, a recessive mutant marker for chromosome 3), confers no detectable resistance to organophosphorus or carbamate insecticides and differs from *kdr* only in its greater or much greater resistance towards DDT-like compounds and the pyrethroids (Table 2).

Three- to five-day-old female houseflies of the four strains were treated at room temperature with the compounds dissolved in acetone, and were held either for 48 h at 20 °C or 3-4 d at 15, 20 and 28 °C, and were checked daily for numbers killed. Of the carbinols tested (Table 1) only dicofol and FDMC had relatively strong insecticidal activity.

DDT and four of its analogues (Table 1) produced typical symptoms of DDT poisoning in the susceptible and three of the resistant flies. These symptoms are increased activity, tremors,

incoordination and tetany. Toxic symptoms were delayed in the resistant flies, particularly in the Super-*kdr* strain, in which they became visible at least several hours after treatment with DDT. The carbinols produced different symptoms which were the same for all the strains tested. The initial sign of poisoning, increased locomotor activity, was first apparent several hours after treatment even at the strongest dose and the highest holding temperature. The insects then exhibited transient collapse with a rapid return to normal activity. The periods of prostration, initially infrequent and very brief, increased in duration and frequency until the insects were no longer able to right themselves or walk. Tremors, incoordination of the limbs and increased wing-beat observed in DDT-poisoned flies were absent or rare in the carbinol-treated insects. Paralysis was neither induced nor reversed by altering the holding temperature, but the insects were killed faster at the higher temperature. At death (end-point), the relative toxicities of the carbinols varied relatively little for the three holding temperatures (Table 3), but those for DDT and its analogues were negatively correlated with temperature (Table 3) in all strains except Super-*kdr*, which had a positive temperature coefficient for DDT (Table 3). This is almost certainly due to the very slow action of this compound against those flies at 20 and 15 °C, temperatures at which death is delayed well beyond 4 d. Perthane, which acts much faster against Super-*kdr* flies than DDT, gave a negative temperature coefficient.

The other major difference with the carbinols was the slight or negligible resistance of the DDT-resistant strains to these compounds (Table 3). This lack of effect by major known mechanisms of resistance to DDT in the housefly was unexpected, particularly so for *kdr*, which is believed to alter either access of insecticide to the site of action, or the site of action itself, presumably a nerve-membrane receptor for DDT-type insecticides¹. (*kdr* confers resistance to DDT analogues that

cannot be dehydrochlorinated and is responsible for low nerve sensitivity to DDT directly applied to the thoracic ganglion⁴). Dicofol and FDMC are therefore not only potent inhibitors of DDT dehydrochlorinase but also affect a site of action different from that primarily affected by DDT. This site is unknown, but several enzymes are known to be affected by DDT⁵, particularly the oligomycin-sensitive Mg^{2+} ATPase⁶. Chang and Cutkomp⁷ have demonstrated that inhibition of this enzyme in cockroach muscle by DDT, TDE, methoxychlor and DDE has a negative temperature coefficient, whereas the activity of dicofol and chlorphenethol increases with temperature.

It is interesting to speculate whether the major target of attack by carbinols in acarines is similar to that in houseflies, as acarines are very susceptible to most of the carbinols tested here but are unaffected by DDT and many of its analogues. Also, it remains to be seen whether the slow toxic action described here is confined only to the carbinol analogues of DDT, as the screening procedures used so far for bioassays on analogues of DDT were not designed to detect this type of action.

I thank Dr I. J. Graham-Bryce for discussions, Ciba-Geigy and Murphy Chemical for some of the carbinols, and Drs J. Keiding and A. W. Farnham for two of the resistant strains of houseflies.

Chloroquine enhances Epstein-Barr virus expression

AFRICAN Burkitt's lymphoma (BL) is a malignant tumour of children most common in areas having holoendemic malaria^{1,2}. It occurs with a particularly high frequency in certain areas of Africa³, with sporadic cases in other areas including Europe and North America^{4–7}. Malaria has been shown to have immunosuppressive effects^{8,9}, and chronic malaria, in particular, causes repeated stimulation of the immune response to infections with plasmodia. It has also been proposed that the immunosuppressive action of malarial drugs may make the immune system more susceptible to cancer and may contribute to BL development. Chloroquine is widely used as an anti-malarial agent and also in the therapy of connective tissue diseases^{10,11}. It is thought to act by forming molecular complexes with plasmodial DNA, causing inhibition of plasmodial DNA synthesis^{12–14}. It has been suggested that chloroquine may play a part in the development of BL¹⁵. Another factor thought to be involved in the aetiology of the African form of BL is the Epstein-Barr virus. Virtually all BLs are EBV genome-carrying tumours and patients have high titres of antibody against EBV^{16,17}. The most widely proposed hypothesis is that BL is due to EBV-induced malignant transformation of thymus-independent B lymphocytes^{17,18}. It has been shown *in vitro* that EBV can induce transformation of resting human and simian lymphocytes which become established as permanent lines^{19,20}. Almost all the cells in these lines contain EBNA (the EBV-induced nuclear antigen) and carry multiple copies of EBV DNA^{21,22}. It has also been shown that EBV can induce lymphomas in experimentally infected monkeys²³. However, the failure of EBV infection to have serious adverse effects in the great majority of humans indicates that interaction with some

other factor, such as malaria or antimalarial drugs, must be involved in BL pathogenesis. We report here studies on the effect of chloroquine on the expression of EBV antigens. The data obtained indicate that chloroquine can activate the EBV cycle and the expression of EBV antigens.

EBV-infected cells express one or more of the EBV-induced antigens, which are readily detectable by immunofluorescence with the use of human sera containing anti-EBV antibodies. These antigens include EBNA, early antigen (EA), virus capsid antigen (VCA) and membrane antigen (MA). The cell line used here was Raji²⁴, which is EBNA-positive, EA-negative and VCA-negative. The cells were grown in medium RPMI 1640 supplemented with 10% heat-inactivated fetal bovine serum, penicillin (100 U ml⁻¹) and streptomycin (100 µg ml⁻¹). Raji cells were superinfected with P3HR-1 strain of EBV²⁵ for the induction of EA and VCA. Drug treatment was carried out as follows: 2×10^6 lymphoid cells were sedimented by low-speed centrifugation and the cells were washed three times with phosphate-buffered saline (PBS). The pellet was dispersed and incubated at 37°C in 5 ml of medium containing chloroquine (diphosphate salt, Sigma) at concentrations of 0, 0.1, 1.0, 5.0 µg ml⁻¹ (0, 1.9×10^{-7} , 1.9×10^{-6} , 9.5×10^{-6} M). Six tubes were prepared for each treatment and the viability of the cells (as determined by the trypan blue exclusion test) was estimated after 20–24 h. Only cell preparations which contained less than 5% nonviable cells were used for EBV infections. 200,000 cells from each of these preparations were pelleted by low-speed centrifugation. The supernatant was discarded and 0.1 ml virus suspension was added per pellet, except to the control. The virus-cell mixture was shaken gently, 1 ml of medium containing the appropriate amount of chloroquine was added and the cultures incubated for 48 h at 37°C. Cells were then collected, washed three times in PBS and resuspended in it. Four smears were prepared from each culture, dried in air at room temperature, and fixed in a 1:1 mixture of acetone-methanol at -20°C for 3 min. The smears were kept at -20°C until used for staining by the standard immunofluorescence methods described in Table 1.

The data on the effect of chloroquine on superinfection of Raji cells with P3HR-1 EBV are shown in Table 1. Chloroquine treatment caused a significant increase in EA-positive cells at a concentration as low as 0.1 µg ml⁻¹ (1.9×10^{-7} M). In this regard, it is interesting that plasma concentrations of chloroquine in man during malaria chemotherapy range from 3×10^{-7} to 10^{-6} M (0.16 to 0.53 µg ml⁻¹)²⁶. Above 0.1 µg ml⁻¹ chloroquine, there was no further increase in the number of EA-positive cells. There was no difference in VCA-positive cells in the presence of chloroquine.

In preliminary experiments we found that chloroquine had no effect on EA and VCA in EBV genome-carrying cells not

superinfected by EBV, thus indicating that unlike iododeoxy-uridine²², chloroquine does not induce antigen expression in non-exogenously infected cells.

The results presented here clearly indicate that chloroquine increases EA expression in superinfected cells. This suggests that chloroquine may be acting either directly on the exogenous EBV genome or indirectly by activating cellular mechanisms essential for the expression of the exogenous EBV genome.

It is well known that BL patients have high antibody titres against EBV antigens^{16,17}. In the present study, chloroquine gave rise to an increased expression of EA, an EBV antigen, which *in vivo* would be expected to provoke an increased antibody reaction. It would therefore be useful to compare levels of antibody titres in BL patients who received chloroquine therapy with control BL patients who were never treated with this drug.

Although the exact mechanism by which chloroquine treatment affects viral expression is unknown, one possibility is that chloroquine alters the relationship between DNA and cellular controls and this hypothesis is now being investigated. Chloroquine can also form molecular complexes with DNA and inhibit DNA-dependent nucleic acid polymerase reactions^{12–14}.

In conclusion, the present study suggests that chloroquine may play an important part in the development of African Burkitt's lymphoma by enhancing the expression of EBV, an oncogenic human herpesvirus. This does not exclude a further contribution resulting from the immunosuppressive action of chloroquine.

Table 1 Effect of chloroquine on % EA-positive cells

	Raji	Raji+EBV	Raji+EBV+chloroquine (µg ml ⁻¹)		
			0.1	1.0	5.0
EA	0	6.5±0.95	19.0±1.61 (P<0.001)	16.8±1.83 (P<0.001)	18.3±1.97 (P<0.001)

The tests for EA and VCA were carried out by indirect immunofluorescence. The smears were incubated at room temperature for 45 min with anti-EA serum LM (with EBNA-positive, EA-positive and VCA-positive antibody composition) diluted 1:20, and with anti-VCA reference serum JM diluted 1:10. These smears were washed three times with PBS and incubated for 45 min with anti-IgG conjugate (Highland) diluted 1:30. The smears were then washed again three times with PBS, counterstained with Evans blue for 10 min, washed three times with PBS and mounted on a slide in a 1:1 mixture of glycerol-PBS. Raji cells were used as control for EA and B95-8 cells¹⁹ as control for VCA. EA- and VCA-positive cells were estimated as a % of approximately 300 cells. Each concentration was tested in six cultures and the results show the mean ± s.e.m.

Asbestos-mediated membrane uptake of benzo[a]pyrene observed by fluorescence spectroscopy

EPIDEMIOLOGICAL evidence indicates that particulate matter, such as asbestos, can increase the health risk from exposure to chemical carcinogens. For example, asbestos insulation workers show an eightfold increased disposition towards lung cancer; non-smokers had only a slightly increased risk of lung cancer, whereas the smokers had a 92-fold increased risk^{1,2}. These data indicate that 90% of the asbestos related cancers are the result of the co-carcinogenic effects of cigarette smoking and the inhalation of asbestos fibres. We have now examined one possible mechanism of co-carcinogenesis—the ability of particulate matter to increase the rate of cellular uptake of benzo[a]pyrene (BP). We used fluorescence spectroscopy to investigate the ability of two particulates, silica and asbestos, to adsorb BP, and to deliver the carcinogen to model membranes. The surface area of the asbestos sample was 60-fold less than that of our silica sample. Surprisingly the asbestos sample showed a greater ability to adsorb BP in a monomeric state than silica. Most importantly BP which is adsorbed to asbestos is more rapidly transported into membranes than BP which is adsorbed to silica. Thus increased cellular exposure to carcinogens, resulting from the presence of particulates which can adsorb and deliver these carcinogens to cells, may be involved in the process of co-carcinogenesis.

Figure 1 shows fluorescence emission spectra of BP in dilute benzene solution, and of a suspension of BP crystals in aqueous buffer. A structured emission is observed from BP dissolved in benzene, whereas the suspension of BP crystals yields a broad structureless emission at longer wavelengths. This latter emission results from formation of an excited state charge-transfer complex between two or more adjacent BP molecules³ and is called the excimer emission. The fluorescence emission spectra may therefore be used to reveal the proximity of BP molecules to one another. Also shown in Fig. 1 is the fluorescence emission spectrum of BP which is partitioned into lipid bilayers after uptake from asbestos fibres. Only the structured emission is observed which is indicative of widely dispersed BP molecules.

Fig. 1 Fluorescence emission spectra of benzo[a]pyrene. Emission spectra are shown for BP in benzene (—), and as a suspension of crystals in aqueous buffer (---). After addition of DPPC vesicles to asbestos containing adsorbed BP (· · ·) the emission spectra closely resembles that of BP in benzene.

Fig. 2 Fluorescence emission spectra of benzo[a]pyrene. Normalised emission spectra for BP microcrystals (· · ·), and for BP adsorbed to 8.6 mg silica (---) and 9.5 mg asbestos (—). In each case the sample was suspended in 10 ml of buffer, and contained 5 μ g BP.

Figure 2 shows the fluorescence emission spectra of BP when present as microcrystals which are suspended in aqueous buffer, and when the BP is adsorbed to silica or the amosite, which is the form of asbestos used in our studies (see Table 1 legend for experimental details). The emission spectra of the microcrystals and of the silica-adsorbed BP are similar, indicating the presence of BP microcrystals on the silica surface, or the presence of BP crystals which did not adsorb to silica during the solvent evaporation process. The emission spectra of the asbestos-adsorbed BP is dominated by the structured emission, indicating the presence of monomeric adsorbed BP. The superior ability of amosite to disperse BP is especially surprising when the surface areas of these two particulates are compared. As determined by nitrogen adsorption these surface areas are 5.7 and 381 $\text{m}^2 \text{g}^{-1}$ for asbestos and silica, respectively⁴⁻⁶.

The fluorescence emission spectra of BP are sensitive to both the weight percentage of carcinogen which is on the particulate and to the age of the samples. Over a period of weeks after preparation the emission spectra of BP on the silica samples becomes more structured and shows less excimer emission. We do not know what factors control this process, but temperature of sample storage and the presence of residual solvent do not seem to affect the rate of sample ageing. Less significant changes occur with asbestos-adsorbed BP. Irrespective of these considerations we consistently observed more BP excimer emission from the silica than from the asbestos samples. These observations include BP-to-particle weight ratios ranging from 3 to 0.1 mg BP per gram of particulate. For both particulates the excimer emission is less pronounced at the lower weight ratios (Table 1).

Emission spectra of aqueous suspensions of particles which contain BP retain a constant intensity and shape over a period of hours. On addition of phospholipid vesicles, an increase in fluorescence intensity occurs at 405 nm. Simultaneously the excimer emission disappears. After complete transfer of BP to the lipid bilayers the emission spectra of all samples listed in Table 1 become identical to that of BP in lipid bilayers (Fig. 1). Thus, significant decomposition of BP on the surface of the particles did not occur.

BP is only slightly soluble in water, so it seems likely that BP crystals will have a cellular availability which is limited by its rate of solubilisation in the aqueous phase. A particulate which adsorbs and disperses BP in a monomeric state could therefore facilitate BP solubilisation and hence increase cellular availability. The transfer of BP from the particulate's surface to the lipid

bilayer is conveniently quantitated by the increase in fluorescence intensity at 405 nm. The percentage of BP transferred is calculated from

$$\% \text{ BP transferred to membrane} = \frac{I(t) - I_0}{I_\infty - I_0}$$

where I_0 is the fluorescence intensities at 405 nm before addition of membranes, I_∞ is the intensity after complete transfer, and $I(t)$ the intensity at time t .

Figure 3 compares the membrane uptake rate of BP from the three states. As a model membrane we used single bilayer vesicles of dipalmitoyl-L- α -phosphatidylcholine^{7,8}. Asbestos-adsorbed BP shows the most rapid rate of membrane uptake, and the microcrystals of BP the slowest rate. Table 1 lists the time required for 50% transfer of BP for particulate samples with a range of BP-to-particulate weight ratios. Asbestos is more effective than silica at all weight ratios, with the most dramatic effect being observed at the lower ratios. Asbestos or silica, when added to preformed microcrystals of BP in buffer, did not increase the rate of BP membrane uptake or alter the shape of the fluorescence emission spectra of the suspended microcrystals. Therefore, only BP which is adsorbed to the particles displays an increased rate of membrane uptake. These rates increased as surface density of BP on the particulates decreased.

Our results clearly demonstrate that a particulate with a known co-carcinogenic effect is also effective in the dispersal and transport of benzo[a]pyrene. This observation may partially explain the co-carcinogenic effects of particulates and polynuclear aromatic hydrocarbons⁹⁻¹¹. Presumably a carcinogen must enter a cell before transformation, and such entry must involve transport of the polynuclear aromatic hydrocarbon across the plasma membrane. The lungs have mechanisms whereby particulates are cleared, these being phagocytosis by the lung macrophages and upward ciliary action followed by ingestion¹². Particulate matter which increases the rate of carcinogen transport could therefore increase the effective dose of carcinogen before clearance by these protective mechanisms. This speculation is supported by observations which indicate that soot particles which have been isolated from human lungs no longer contain BP¹³.

Particle-enhanced transport of carcinogens is unlikely to be the only mechanism of co-carcinogenesis. Studies with experimental animals have shown that the inhaled particulate haematite is co-carcinogenic with the injected systemic carcinogen diethylnitrosamine¹⁴. The tumours are localised in the lungs, which are the sites of particle deposition. However, particulate

matter is unlikely to facilitate carcinogen uptake in these conditions where exposure to particulates and carcinogens is by different routes of administration.

Epidemiological studies have correlated human exposure to asbestos with the incidence of mesothelioma, but this cancer

Table 1 Benzo[a]pyrene uptake by phospholipid vesicles from particulate adsorbed and microcrystalline states

mg BP per g particulate	Time for 50% uptake (min)		(Monomer emission) [†]	
	Silica	Asbestos	Silica	Asbestos
0.1	4.5	3	0.32	0.34
0.3	24	6.5	0.24	0.34
1.0	30	12	0.19	0.28
3.0	34	17	0.23	0.22

BP Microcrystals	Time for 15% uptake (min)	(Monomer emission)
		(Total emission)
No particles	23	0.17
+ Amosite*	24	0.21
+ Silica*	24	0.19

Benzo[a]pyrene (BP) 99 + % purity was from Aldrich lot 101847 used without further purification. BP concentrations were obtained using a molar extinction coefficient of $57,500 \text{ M}^{-1} \text{ cm}^{-1}$ at 299.4 nm. Silica was obtained from preparative thin-layer chromatographic plates, $20 \times 20 \text{ cm}$, $1,000 \mu\text{m}$ thick (Analabs). The surface area of this sample, as determined by nitrogen adsorption, was $381 \text{ m}^2 \text{ g}^{-1}$. The particle size distribution is heterogeneous, with most particles being between 1.5 and $15 \mu\text{m}$ in diameter, and an average size of about $3 \mu\text{m}$ (ref 6). Amosite served as reference asbestos sample (International Union Against Cancer, Johannesburg). The surface area determined by nitrogen adsorption is $5.6 \text{ m}^2 \text{ g}^{-1}$. The particle size distribution is heterogeneous, ranging from 1.5 to $10 \mu\text{m}$, with the average size $2 \mu\text{m}$. For more detailed information on size and chemical composition see ref. 5. Particulate samples containing BP were prepared by mixing the particulate with a benzene solution of BP, followed by evaporation of the benzene under reduced pressure. 0.1 to 3.0 mg of BP was added for each g particulate. The volume of benzene added was always adequate to wet the entire particulate sample, typically 5 or 6 ml of benzene per g of particulate. The sample was rotated continuously during the benzene evaporation. After the sample appeared dry it was kept under vacuum for 30–45 min at 85°C . At the higher weight ratios BP crystals could be seen on the walls of the glass vessel. Any material which clung to the walls was discarded. After removal from the vessel the particulates were stored in the dark under an argon atmosphere. The amount of BP present on the particles was determined by solvent extraction using a Soxhlet extractor. Typically the extraction was continued for 4.5 h (about 50 individual extractions). All extractions were done in duplicate. The fluorescence emission spectra of the extracted material were identical to that of the starting material. Thus there seemed to be no degradation of BP on this particulate which interfered with our measurements. The amounts of BP adsorbed to silica and asbestos, were found to be $85 \pm 15\%$ of the amount added. Aqueous dispersions of BP crystals were prepared by evaporation of a benzene solution of BP to dryness, addition of buffer, followed by sonication for 30 min at 40 W using a Cole-Parmer Model 8845-2 water bath-type sonicator. We will refer to this preparation as being microcrystalline. In all studies the buffer was 0.01 M Tris-HCl, 0.05 M KCl, $\text{pH} = 7.5$. Phospholipid vesicles of dipalmitoyl-L- α -phosphatidylcholine were prepared by ultrasonic irradiation of the lipid suspended at 10 mg ml^{-1} . Sonication was performed using a Heat Systems Model 350 for 10 min at $\sim 50^\circ \text{C}$. Power input was $\sim 200 \text{ W}$. Vesicles were then centrifuged at $54,000 \text{ g}$ for 60 min. All fluorescence spectral data were obtained on an SLM Instruments, computerised photon counting spectrofluorometer (excitation wavelength, 296 nm; excitation and emission band-passes 8 and 4 nm, respectively; excitation filter, Corning 7-54; emission filters, 0-52 and 2 mm of 1 M NaNO_2). BP uptake was measured by the intensity increase at 405 nm. The emission filters do not transmit light below 395 nm. Without these filters we do observe a background signal from the asbestos and silica. Some background signal was seen above 395 nm, typically $<10\%$ of the total intensity. These backgrounds were quantitated using particles without BP, and subtracted from the spectra shown. Spectral data were obtained using a $2 \times 2 \text{ cm}$ cuvette, 4 cm high, which was thermostated and positioned on a magnetic stirrer so that the stirring bar stayed below the light path. Stirring was required to keep the particles or crystals in suspension. The exciting beam impinged upon the sample at an angle of 20° , and the emission observed from this illuminated surface was at 90° to the exciting light. For all the BP uptake kinetics reported here we used $5 \mu\text{g}$ of BP and 10 mg of DPPC. An amount of particulate containing $5 \mu\text{g}$ BP, or $5 \mu\text{g}$ BP crystals, was suspended in 10 ml of buffer. After measurement of the initial intensity 10 mg of DPPC were added in 1 ml of buffer to initiate the reaction. All measurements were performed at 25°C . Complete BP transfer to the bilayers was obtained by heating of the sample to 55°C for 30 min. The final fluorescence intensity was measured after equilibration at the experimental temperature of 25°C .

* Particles were added after formation of the microcrystals.

[†] This value was estimated from the ratio of area under the fluorescence emission spectrum from 380 to 440 nm to the total area from 380 to 605 nm. After complete uptake of BP by vesicles this ratio is 0.47.

Fig. 3 Rate of benzo[a]pyrene uptake in to lipid bilayers. The % of benzo[a]pyrene transferred to DPPC vesicles is shown for microcrystals of BP (○), silica adsorbed BP (△), and amosite adsorbed BP (□).

does not seem to be correlated with cigarette smoking¹⁵. Particulates such as fibrous glass¹⁶, asbestos^{10,11} and many other types of foreign bodies¹⁷ seem to be carcinogenic without deliberate exposure to chemical carcinogens. In fact, most types of cellular trauma and scarification will predispose the damaged areas to neoplastic transformation^{18,19}. Therefore it is clear that mechanisms other than particle enhanced transport are operative in carcinogenesis. The fluorescence methodology described here is useful with other polynuclear aromatic hydrocarbons⁶ and with nitrogen heterocyclic compounds²⁰. The ability to quantitate the delivery of carcinogens to cells should aid in elucidating the multiple etiology of carcinogenesis.

Electromechanical properties of articular cartilage during compression and stress relaxation

THE main physiological function of articular cartilage is to act as a bearing material. It consists of an organic matrix made of collagen, proteoglycans, non-collagenous proteins, lipids and cells that are swollen with water^{1,2}. Its net fixed charge is negative and directly proportional in magnitude to its hexosamine content at each depth³. When cartilage is compressed, interstitial fluid is exuded. This flow of fluid with respect to the solid matrix plays an important part in controlling various rheological properties of the tissue, such as its creep deformation under load^{4–11}. Also, we have observed that measurable electrical potential differences are induced between the surface and deepest regions of cartilage when it is compressed. We report here our studies of this phenomenon to quantitatively relate the magnitude, sign and time dependence of the electrical potentials to the known features of cartilage mechanics and fluid flow¹¹, that is, in terms of tissue structure, function and composition. Our results suggest that an electrokinetic mechanism is primarily responsible for the mechanical-to-electrical transduction response.

Mechanically induced potentials in cartilage have been observed previously^{12,13} when a load was applied to one region of a hydrated specimen while electrodes were generally located

Fig. 1 Experimental configuration for measurement of electrical potential V_0 and mechanical stress σ due to an imposed strain ϵ and strain rate $\dot{\epsilon}$.

in an adjacent region. However, in these experiments the mechanical stress, strain and the fluid velocity field were so complex that it was difficult to relate quantitatively any induced electrical field to the mechanical fields. In our studies, therefore, a geometrical configuration was chosen so as to induce and measure electric fields that are colinear with the axial strain field. This enabled us to compare nonequilibrium electromechanical and mechanical rate (for example, transport) processes.

Circular disks of articular cartilage were compressed in a confining chamber with a chlorided silver rod against a porous Ag/AgCl platen (Fig. 1). The articular surface was positioned against the platen. During and after compression, the stress σ and the potential difference V_0 were measured. (The latter was monitored continuously with a Keithley 602 electrometer and a Tektronix 555 oscilloscope.) When final, time-invariant values of σ and V_0 were attained, the tissue was further compressed to a new strain, at the same strain rate $\dot{\epsilon} = 15\%$ per sec, and the procedure was repeated. Strains in the range of 5–20% were attained with each compression, corresponding to compressions of ~ 0.06 – 0.2 mm. These strains resulted in peak stress levels for normal plugs that ranged over 250–650 p.s.i. (17 – 44×10^6 dyn cm⁻²). The apparatus was a modification of that used previously¹⁴ to study stress relaxation behaviour of articular cartilage.

To ensure that the measurements reflected the properties of the full thickness of the tissue, 40 plugs of cartilage and bone were cut from the parapatellar region of 14 medial femoral condyles of adult steers using a previously described procedure¹⁵. The underlying bone was then removed around the tide mark; the resulting cartilage plugs were 2.6 mm in diameter and ~ 1.0 – 1.5 mm thick when fully hydrated. (However, plugs with a ≥ 1 mm region of bone gave similar results.) The plugs

Fig. 2 Potential (●) and stress (○) history for three successive compressions (a–c) of the same normal plug. ϵ , Cumulative strain: 12.7% (a), 26.4% (b) and 39.4% (c). $\dot{\epsilon}$, Strain rate = 15% s⁻¹ (a–c).

were prepared from tissue that was previously frozen. To assess the effect of such storage, five fresh plugs were prepared from one condyle and tested within 3 h of killing the animal, during which time the tissue was kept at 5 °C. Experiments were also carried out with nine plugs that had been partially digested with testicular hyaluronidase. The conditions used decreased the hexosamine content of the tissue by ~75% (ref. 16), and hence reduced its net negative charge. The plugs were equilibrated in 0.15 M NaCl at 4 °C for at least 1 h before use; longer equilibration times gave the same results. Also, one series of both the normal and enzymatically digested samples were equilibrated in 0.15 M NaCl at pH 2.8, and another series of normal plugs was equilibrated with 5 M NaCl at neutral pH.

The pertinent features of the electromechanical response are typified by the data of Figs 2 and 3. Figure 2 shows the time history of V_0 and σ for three successive compressions of a disk of cartilage equilibrated in 0.15 M NaCl at neutral pH. During the compression phase, $t < T$, $V_0(t)$ was positive and increased linearly with $\sigma(t)$ until time $t = T$ when compression was stopped. The ratio (V_0/σ) at $t = T$ always decreased monotonically with successive compressions at the same strain rate, $\dot{\epsilon}$ (Fig. 2). During the relaxation phase, $t > T$, both $V_0(t)$ and $\sigma(t)$ decreased; the decay with time of V_0 and σ was almost identical after the first compression. With each successive compression, these decay times were longer, but $\sigma(t)$ decayed at a successively slower rate than $V_0(t)$. Although the asymptotic stress was usually finite and progressively larger at the end of each successive compression relaxation cycle, V_0 typically relaxed to zero. These data were obtained with plugs that had been stored in the frozen state, but the results obtained with fresh samples were qualitatively identical.

The compression of enzymatically treated plugs equilibrated at 0.15 M NaCl, neutral pH, resulted in potentials positive in sign but reduced in magnitude by 45–75% (Fig. 3a). A similar result was obtained with normal plugs that had been equilibrated in 0.15 M NaCl, pH 2.8. However, all plugs that were enzymatically treated and equilibrated at pH 2.8 gave negative $V_0(t)$ values (Fig. 3b). Finally, the compression of normal plugs equilibrated in 5 M NaCl resulted in potentials that were drastically reduced in magnitude.

A comparison of the electrical and mechanical rate processes that were highlighted in this study suggests the importance of interstitial fluid flow in the observed electromechanical coupling phenomena. The movement of fluid and concomitant matrix reorientation is thought to control the stress relaxation of articular cartilage^{11,14}. Here, the sign and time dependence of V_0 on pH and neutral salt concentration suggest that the potentials are directly related to the flow of fluid and entrained counter-ions with respect to the net negatively charged solid matrix, that is, that an electrokinetic mechanism is dominant.

In the absence of other mechanisms, an electrokinetic model would predict the relaxation of the potential to zero on cessation of fluid flow, as was seen. Further, the observed decrease in (V_0/σ) at $t = T$ with increasing $\dot{\epsilon}$ is consistent with the known¹⁷ increase in fluid flow resistance at higher $\dot{\epsilon}$. The instances of negative V_0 (Fig. 3b) would indicate that the combination of proteoglycan extraction and carboxyl group neutralisation changed the sign of the net matrix charge from negative to positive. Furthermore, the decrease in V_0 at high NaCl concentration is consistent with a screening of the effective fixed charge by mobile neutral salt ions, that is, a decrease of the electrokinetic ζ potential. Similar effects of pH and ionic strength have been seen with collagen membranes^{18,19}. The effect of pH on the dissociation of proteoglycan and collagen charged groups has also been reported^{20,21}. These results^{18–21}, together with the fact that streaming potentials have been induced *in vitro* using an applied pressure gradient but without varying the strain²², also support our conclusion.

Although electrochemical processes may contribute to the measured V_0 (for example, changes in interfacial Donnan equilibrium potentials, or nonequilibrium diffusion potentials due to strain-induced concentration gradients), their contribution was

Fig. 3 Potential (●) and stress (○) history with a, enzymatically treated plug pre-equilibrated in 0.1 M NaCl at neutral pH ($\epsilon = 18\%$). b, Enzymatically treated plug pre-equilibrated in 0.1 M NaCl, pH 2.8 ($\epsilon = 34\%$). $\dot{\epsilon} = 15\% \text{ s}^{-1}$.

probably minimal. This emphasises the importance of considering the kinetics of $V_0(t)$ and $\sigma(t)$. For example, an estimate of the decay of a nonequilibrium concentration gradient and its concomitant diffusion potential, characterised by the diffusion time $\tau_{\text{diff}} \sim \delta^2/2D$, is almost two orders of magnitude slower than that observed for the decay of V_0 (based on a typical specimen thickness δ and internal diffusion coefficients D (ref. 23)). On the other hand, the Donnan interfacial potentials span a distance of a few Debye lengths²⁴. They can re-equilibrate in a time which is of the order of the Debye space charge relaxation time²⁵ (the interstitial fluid dielectric constant divided by its conductivity). This is a negligibly short time on the scale of $V_0(t)$, for relevant ranges of parameter values. On the other hand, the hypothesis that relative fluid flow is intimately linked not only to stress relaxation but to the induced potential V_0 is consistent with the observed similarity of the relaxation of $\sigma(t)$ and $V_0(t)$. This, in addition to our other results, lends further support to the notion that an electrokinetic effect is the dominant rate-limiting process.

The occurrence of mechanically induced electric fields *in vivo*, under equivalent physiological loads, may play an important part in regulating the transport of ions and interstitial fluid. We are now trying to assess quantitatively the influence of chemical modifications of the charge groups within the tissue in order to experimentally and theoretically characterise electromechanical influences on transport. Preliminary results show that compression of samples whose carboxyl groups were blocked (using established reactions²⁶) produces a V_0 that is consistently negative. Finally, we note that the successively differing relaxation rates found for stress as compared with potential (Fig. 2) may provide the first evidence and an important method for assessing the relative contributions of the fluid and solid phases to stress relaxation.

Naloxone reversal of endotoxin hypotension suggests role of endorphins in shock

It is known that the cardiovascular system is extremely sensitive to the effects of both exogenous^{1,2} and endogenous³ opiates. In rats, less than 1% of the morphine dose necessary to produce antinociception results in significant hypotension and bradycardia⁴. The endogenous opiate β -endorphin is stored along with pituitary adrenocorticotrophin (ACTH)^{5,6}, and the action of stressors seems to result in the release of both peptides^{5,6}. Therefore, it seemed likely that β -endorphin is released during shock states and that it might contribute to the hypotension. To test this hypothesis we used an endotoxin shock model^{7,8}. If endotoxin-induced hypotension were mediated through endorphin release, then blockade of endorphins should reverse such hypotension. Using the specific opiate antagonist, naloxone, we not only rapidly reversed endotoxin-induced hypotension, but also prophylactically blocked its occurrence. These findings suggest that endorphins may have a role in the pathophysiology of shock and that narcotic antagonists should be evaluated for their potential therapeutic value in the treatment of shock.

All studies were carried out using conscious rats with chronically indwelling arterial and venous catheters. Two days before experiments, male Wistar rats (Walter Reed strain) weighing 275–300 g were anaesthetised with pentobarbital 50 mg per kg. The tail artery was cannulated by the method of Chiueh and Kopin⁹ for subsequent measurement of blood pressure and heart rate. The external jugular vein was cannulated to allow for intravenous drug injections. Both cannulae were subcutaneously implanted so that they emerged at the back of the neck. The animals had access to food and water ad libitum and were maintained at 24 °C on a 12 h light–dark cycle.

Rats were studied in their home cages with arterial lines connected to a microtransducer (Narco Bio-Systems, model RP1500). Injections of naloxone hydrochloride (Endo Laboratories) or saline were made after administration of *Escherichia coli* lipopolysaccharide endotoxin (Difco, control no. 598159); all injections were given intravenously followed by a 0.3 ml saline intravenous flush to ensure that all of the drug was infused. Blood pressure and heart rate were continuously recorded on a Beckmann dynograph (type R).

Figures 1 and 2 represent the effects of treatment after injection of 4 mg endotoxin per rat. Usually within the first 5–15 min after endotoxin a precipitous fall in blood pressure occurred. When the mean arterial pressure (MAP) dropped to

Fig. 1 Effects of intravenous saline (top) and naloxone (bottom) on the precipitous fall in blood pressure produced by 4 mg endotoxin in representative rats. Either saline (0.3 ml) or naloxone was injected when MAP fell to 65–70 mm Hg (torr). The prominent effect of the cannula flush (0.3 ml, bottom) is related to the clearing of residual naloxone from the line.

our pre-established criterion of 65–70 mm Hg (torr)⁸, an equivalent volume of either saline or naloxone 10 mg per kg was given by intravenous bolus.

Figure 1 shows the effects of saline and naloxone on endotoxin-induced hypotension in representative rats. In marked contrast to saline, which had only a minor transitory effect (Fig. 1, top), within 5 s after naloxone injection both MAP and pulse pressure were restored to pretreatment values (Fig. 1, bottom). The striking differences between naloxone-treated and saline control rats are further demonstrated by grouped data shown for the 5-min interval after endotoxin-induced hypotension (Fig. 2); again, a rapid return of MAP and pulse pressure towards control levels can be seen following naloxone injection. Naloxone in the absence of endotoxin (Fig. 2, solid line) was without effect on either MAP or pulse pressure.

A comparison of the effects of naloxone pretreatment with saline controls over a 2-h period after endotoxin administration is seen in Fig. 3. Due to the short biological half life of naloxone¹⁰, the initial 10 mg per kg dose of this drug was repeated every 30 min; saline controls were also treated at these same intervals. Although the same general pattern of changes was observed in both groups (Fig. 3), the saline control animals exhibited two hypotensive episodes (10 and 45 min after endotoxin administration) during which blood pressure values were significantly lower than before endotoxin (repeated measurement analysis of variance using Hotelling's T^2 statistic¹¹, $F = 12.29$, $P = 0.003$). By contrast, naloxone-pretreated animals did not show significant declines in blood pressure after endotoxin administration ($F = 0.83$, $P = \text{NS}$).

The reversibility of endotoxin-induced hypotension over a 2-h period is represented in Fig. 4. After injection of 8 mg endotoxin, animals were randomly divided into two equal

Fig. 2 Results of various drug injections on mean arterial blood pressure (top) and mean pulse pressure (bottom). Measurements at $t = 0$ began 5 s after intravenous catheter flush. Naloxone alone (●) did not significantly change either measure. Endotoxin 4 mg intravenously resulted in a significant drop in MAP and pulse pressure from control levels (Student's t test, $P < 0.01$ both groups). Subsequent naloxone injection reversed the drop in MAP and pulse pressure (▲), whereas saline injections (○) were without effect. Points represent averages $\pm$ s.e.m. Naloxone doses 10 mg per kg.

groups. One-half received naloxone 10 mg per kg and the other half saline; these were given only after individual MAPs had dropped to 65–70 torr. Animals receiving naloxone after endotoxin-induced hypotension had significantly higher MAP than those receiving saline (analysis of variance¹², $F = 10.55$, $P = 0.009$).

In addition to blood pressure effects, heart rate was also measured. In the saline control group, heart rate data tended to parallel the blood pressure changes, the lowest average heart rate being observed 55 min after injection (347 ± 33 beats per min, $n = 4$) followed by an increase to significantly higher values at 120 min (453 ± 17 beats per min, $n = 4$, Student's $t = 2.86$, $P < 0.02$). In naloxone-pretreated rats, subsequent injection of endotoxin had no effect on heart rate.

The results of this study clearly demonstrate that naloxone not only blocks but also reverses the hypotensive effects of endotoxin. Heart rate changes after endotoxin also seem to be

Fig. 3 Effects of naloxone pretreatment on 2 h MAP measurements after endotoxin. Pretreatment with naloxone 10 mg per kg (●) blocked the effects of 4 mg endotoxin on MAP. The groups treated with 4 mg endotoxin alone (○) had significantly lower MAP values compared with pre-endotoxin control values (see text). Vertical bars are $\pm$ s.e.m.

blocked by naloxone. During these experiments the administration of naloxone was discontinued after 2 h (Fig. 3), and survival was not affected. Studies are in progress to evaluate the effects of more prolonged naloxone administration.

The efficacy of the specific opiate antagonist, naloxone, as a modifier of physiological and behavioural events has been used as a tool to infer endorphin involvement in various systems^{13–15}. From that perspective, the effects of naloxone in these present studies implicate endorphin as a factor in endotoxin shock. Interestingly, it has often been suggested that bacterial endotoxins result in the secondary release of endogenous substances which, in turn, may cause some of the cardiovascular effects associated with this form of shock^{7,8}. Our studies suggest that endorphin may be one of these postulated substances.

Endotoxins are known to result in the secretion of ACTH from the pituitary, presumably by activation of hypothalamic releasing factors¹⁶. It has been shown recently that both ACTH and β -endorphin are stored in common pituitary sites and concomitantly regulated^{5,6}. It seems probable that endotoxins would therefore also release pituitary β -endorphin. Moreover, it seems likely that the established therapeutic efficacy of synthetic corticosteroids^{3,17} in the treatment of shock may be a partial consequence of their inhibitory effects on pituitary β -endorphin release⁵. The enhanced sensitivity of adrenalectomised animals to shock states¹⁸ as well as to intravenous β -endorphin injections¹⁹, both of which are attenuated by corticosteroid pretreatment, are also consistent with the hypothesis that endorphin release is important in the pathophysiology of shock.

The effect of naloxone in reversing the early hypotension of endotoxin shock suggests that naloxone may be efficacious in the

Fig. 4 Reversal of endotoxin shock by naloxone. After injection of 8 mg endotoxin, rats were injected with naloxone 10 mg per kg (▲) or saline (○) after MAP reached 65–70 torr. Large arrows indicate approximate times of naloxone injection. Some animals required two naloxone injections because the hypotensive effects produced by endotoxin were biphasic. Naloxone injections significantly improved MAP (see text). Vertical bars are $\pm$ s.e.m.

treatment of septic shock. The possibility that the endogenous opiates may also be involved in the pathophysiology of other shock models is currently being investigated in our laboratory.

We thank Drs M. Woods and J. L. Meyerhoff for advice and Dr T. Jacobs, Dr R. McCarty and J. Quinn for their help.

Nicotinic cholinergic stimulation increases cyclic GMP levels in vertebrate skeletal muscle

CYCLIC GMP seems to be an intracellular second messenger for certain actions of acetylcholine at muscarinic receptors (for a review, see ref. 1). For example, previous studies have provided evidence that activation of muscarinic, but not of nicotinic, cholinergic receptors leads to an increase in the level of cyclic GMP in many tissues^{2–8}, including smooth muscle^{3–5}. Also, it has been demonstrated that contraction of cross-striated muscle fibres of the giant barnacle elicited by nerve stimulation is associated with an increase in the level of muscle cyclic GMP⁹.

These observations prompted us to determine whether a similar cyclic GMP increase is associated with contractile activity in vertebrate skeletal muscle. We report here that activation of a nicotinic cholinergic synapse raises the level of cyclic GMP in frog skeletal muscle. As in smooth^{4,5} and in barnacle⁹ muscle, this cyclic GMP increase in vertebrate skeletal muscle is a consequence of a neurotransmitter-induced depolarisation of the muscle membrane.

The gastrocnemius muscles of 3–4 inch *Rana pipiens* (northern variety) were used in this study. The cyclic nucleotide content of resting muscles from different frogs varied several-fold, but the levels in the two muscles from a single frog were essentially equal (Table 1, line 1). Therefore, in the experiments described below, one gastrocnemius from each frog served as the test muscle and the other as the control.

When the motor nerve supplying a test muscle was stimulated for 5, 15 or 30 s, in the conditions described in the legend to Table 1, both a maintained tetanic contracture and an increase in the level of muscle cyclic GMP resulted. The increase seemed to be maximal after 15 s, at which time test muscle cyclic GMP concentration was 230% that of the paired control muscle. The effect of stimulation for periods longer than 30 s was not determined because the test muscle fatigued rapidly beyond this point. In agreement with other reports¹⁰, nerve stimulation did not significantly increase the level of cyclic AMP in frog skeletal muscle.

Table 1 Effect of nerve stimulation on cyclic nucleotide levels in frog skeletal muscle

Duration of stimulation (s)	Cyclic GMP % control	Cyclic AMP
Unstimulated	101 ± 7 (9)	105 ± 8 (13)
5	162 ± 21 (7)*	129 ± 20 (7)
15	230 ± 45 (19)†	117 ± 14 (14)
30	192 ± 23 (7)‡	117 ± 13 (6)

Paired gastrocnemii, with nerve supply intact, were removed from each frog and preincubated for 1 h at room temperature in frog saline of the following composition: 111 mM Na⁺, 3 mM K⁺, 1.8 mM Ca²⁺, 117.6 mM Cl⁻, 5 mM MOPS (3-(N-morpholino)propanesulphonic acid), adjusted to pH 7.4 with NaOH. One gastrocnemius from each frog was arbitrarily chosen as the test muscle and the other as the control muscle. After the preincubation period, the motor nerve supplying the test muscle was stimulated by a suction electrode with supramaximal pulses of 0.2 ms duration delivered at 30 Hz for 5, 15 or 30 s. Following this stimulation, the control and test muscles were rapidly homogenised in 4.0–7.0 ml of ice-cold 7% trichloroacetic acid with an Ultraturrax. The homogenates were then centrifuged at 27,000 g for 5 min. The protein content of the pellets was determined by the method of Lowry *et al.*¹⁸. 3.0–3.5-ml aliquots of the supernatants were extracted five times with 10 ml of ether, lyophilised and reconstituted in 0.5 ml of 50 mM sodium acetate–2 mM EDTA (pH 6.2). The cyclic GMP content of the reconstituted samples was measured by the radioimmunoassay method of Steiner *et al.*¹⁹, and the cyclic AMP content by the method of Brown *et al.*²⁰. The recovery of exogenous cyclic GMP and cyclic AMP, added to whole muscle homogenates, was 83% and 89%, respectively. When sodium acetate-reconstituted samples were treated with beef heart phosphodiesterase (Boehringer), the cyclic nucleotide content was reduced to undetectable levels. The cyclic GMP and cyclic AMP concentrations of resting muscles were 0.056 ± 0.006 (mean ± s.e.m.; 28 muscles) and 1.13 ± 0.07 (mean ± s.e.m.; 26 muscles) pmol per mg protein, respectively. The protein levels of the two muscles from a given frog were essentially equal; test muscle protein was 102 ± 2% (mean ± s.e.m.; 22 muscle pairs) that of control muscle. For each muscle pair, results were calculated as (100 (cyclic nucleotide content of test muscle in pmol per muscle)/(cyclic nucleotide content of control muscle in pmol per muscle)). The values represent the mean ± s.e.m. of these data; the numbers in parentheses indicate the number of muscle pairs used in each experiment. Statistical significance was calculated using a two-tailed Student's *t*-test.

* Significantly different from unstimulated, $P < 0.05$.

† $P < 0.02$.

‡ $P < 0.01$.

Table 2 shows the effect of nicotinic and muscarinic cholinergic antagonists on the response of cyclic nucleotides to nerve stimulation. Muscle pairs were preincubated for 1 h in frog saline containing the antagonists, and the motor nerve of the test muscle then stimulated for 15 s. Both nicotinic antagonists, curare (5×10^{-4} M) and α -bungarotoxin (10^{-6} M), blocked the nerve-evoked contraction almost completely, and both compounds abolished the elevation of cyclic GMP in response to nerve stimulation (Table 2, lines 3, 4). The muscarinic antagonist scopolamine (5×10^{-4} M) did not visibly affect the nerve-evoked contraction; nerve stimulation in the presence of scopolamine increased the cyclic GMP level of the test muscle to 190% that of the paired control muscle (Table 2, line 5). The difference between the nerve-stimulated increase in cyclic GMP in the presence and in the absence of scopolamine was not statistically significant (compare lines 2 and 5, Table 2; $P > 0.1$ by Student's *t*-test). These data indicate that the nerve-stimulated increase in cyclic GMP resulted from the activation, by endogenous acetylcholine, of nicotinic, rather than muscarinic, receptors.

To determine whether, as in barnacle and smooth muscle, membrane depolarisation, without neurotransmitter receptor activation, is able to increase cyclic GMP in frog skeletal muscle, muscle pairs were preincubated in frog saline for 1 h after which the test muscle was caused to contract by direct electrical stimulation for 15 s (as described in the legend to Table 2). The isometric tension response of the muscle to direct electrical stimulation was similar to that observed during stimulation of the motor nerve. The cyclic GMP content of the directly stimulated test muscle was 227% that of the control muscle (Table 2, line 6). There was also a slight increase in cyclic AMP in these directly stimulated muscles, but this increase was not statistically significant. The cyclic GMP increase elicited in response to direct electrical stimulation was not due to activation of nicotinic receptors by endogenous acetylcholine released from motor nerve terminals, as this increase was not blocked by the nicotinic antagonist α -bungarotoxin. Thus, a 1-h preincubation in 10^{-6} M α -bungarotoxin, which inhibited neuromuscular transmission, did not visibly affect the electrically stimulated contracture, and direct stimulation in the presence of α -bungarotoxin elevated the level of test muscle cyclic GMP to 192% that of the paired control muscle (Table 2, line 7; lines 6 and 7 not statistically different by Student's *t*-test, $P > 0.1$). These data suggest that depolarisation of the muscle membrane in response to activation of acetylcholine receptors, is a step in the sequence of events by which neuromuscular activity elevates the cyclic GMP level of frog skeletal muscle.

Previous studies had demonstrated that activation of muscarinic, but not nicotinic, cholinergic receptors causes an increase in the level of cyclic GMP in many target tissues; the tissues studied included heart^{2,3}, smooth muscle^{3,5}, brain³, salivary gland⁴, sympathetic ganglia⁶ and exocrine pancreas^{7,8}. The present study of frog skeletal muscle represents the first demonstration of a nicotinic cholinergic-mediated increase in cyclic GMP. Previous failures to observe nicotinic-stimulated increases in cyclic GMP may be explained partly by the fact that many of the tissues examined lack nicotinic receptors and partly by the fact that bath-applied agonists rapidly desensitise the nicotinic, as opposed to the muscarinic, receptor (for a review, see ref. 11).

The present results on vertebrate skeletal muscle and previous studies on invertebrate cross-striated muscle⁹ and vertebrate smooth muscle^{4,5} indicate that, in all three types of muscle, contractile activity is associated with an increase in cyclic GMP. In each case, contractile stimuli which depolarise the muscle membrane, without activating neurotransmitter receptors, also increase muscle cyclic GMP levels; these results suggest that the neurotransmitter increases cyclic GMP levels at least in part indirectly through membrane depolarisation, rather than through direct activation of a neurotransmitter-sensitive guanylate cyclase. Other evidence, obtained in barnacle muscle⁹ and in smooth muscle^{4,5}, suggests that the mechanism by which

Table 2 Effect of cholinergic antagonists on cyclic nucleotide levels in stimulated frog skeletal muscle

Preincubation solution	Mode of stimulation of test muscle	Cyclic GMP % control	Cyclic AMP % control
1. Normal saline	None	101 ± 7 (9)	105 ± 8 (13)
2. Normal saline	Nerve stimulation	230 ± 45 (19)*	117 ± 14 (14)
3. 5×10^{-4} M curare-saline	Nerve stimulation	104 ± 13 (11)	97 ± 10 (6)
4. 10^{-6} M α -bungarotoxin-saline	Nerve stimulation	101 ± 16 (5)	112 ± 14 (5)
5. 5×10^{-4} M scopolamine-saline	Nerve stimulation	190 ± 14 (8)†	118 ± 12 (8)
6. Normal saline	Direct stimulation	227 ± 22 (22)†	138 ± 17 (10)
7. 10^{-6} M α -bungarotoxin-saline	Direct stimulation	192 ± 29 (10)*	111 ± 11 (10)

Paired gastrocnemii, with nerve supply intact, were removed and preincubated for 1 h at room temperature in the indicated solutions. 'Nerve stimulation' indicates that the nerves supplying the test muscles were stimulated for 15 s as described in the legend to Table 1. 'Direct stimulation' indicates that test muscles were placed in a plexiglass chamber and a baffle was fitted around the muscles to divide the chamber into two compartments; supramaximal pulses (1-ms duration; 30 Hz) were applied for 15 s between the two compartments. The values represent the cyclic nucleotide content of the test muscle as the mean $\pm$ s.e.m. of that of the paired control muscle. The numbers in parentheses indicate the number of muscle pairs used in each experiment. Statistical significance was calculated using a two-tailed Student's *t*-test.

* Significantly different from unstimulated (line 1); $P < 0.02$.

† $P < 0.01$.

depolarisation increases cyclic GMP involves an increase in the intracellular concentration of free calcium. A similar mechanism may be responsible for the cyclic GMP increase in frog skeletal muscle.

The role of cyclic GMP in muscle function remains unknown. Ong and Steiner¹², using an immunocytochemical procedure, showed that cyclic GMP is predominantly located over the A bands in unstimulated mammalian skeletal muscle, but the functional significance of this observation has not yet been determined. Cyclic GMP may be part of a positive or negative feedback system for regulating the concentration of free calcium in muscle^{13,14}. Another possibility is that cyclic GMP mediates some of the effects of contractile activity on muscle physiology. For example, contractile activity increases the glucose permeability of vertebrate skeletal muscle¹⁵, and can both maintain muscle mass¹⁶ and prevent the appearance of extra-junctional acetylcholine receptors¹⁷ in denervated mammalian muscle. It is possible that cyclic GMP is the intracellular mediator of one or more of these effects. The observation that contractile stimuli elevate cyclic GMP in several types of muscle indicates that this cyclic GMP increase is of physiological importance.

We thank Dr Thomas Lentz for purified α -bungarotoxin and Dr Robert Study for participating in the early experiments of this investigation and for providing the materials for the cyclic GMP radioimmunoassay. This research was supported by the USPHS.

Effect of guanine nucleotides on striatal dopamine receptors

GUANINE NUCLEOTIDES have been shown to regulate the sensitivity of adenylate cyclase to hormones in several systems¹⁻⁵, including the dopamine-sensitive adenylate cyclase in the caudate nucleus^{2,4}. It has also been reported that in the presence of GTP the affinities of glucagon receptors⁶, β -adrenergic receptors^{7,8}, prostaglandin E_1 receptors⁹ and opiate receptors¹⁰ for agonists are decreased. For β -adrenergic receptors this effect of GTP has been described as 'agonist-specific', as it is seen with agonists but not with antagonists^{7,8}. We report here a similar effect of GTP on the ability of dopamine-receptor agonists to compete for ³H-spiroperidol binding sites on rat striatal membranes. The presence of 0.3 mM GTP led to a four-to-fivefold increase in the K_d values for the inhibition of ³H-spiroperidol binding by dopamine-receptor agonists. No changes in K_d values were observed for antagonists. Dopamine-receptor agonists and antagonists have been defined by the stimulation or inhibition of dopamine-sensitive adenylate cyclase in the neostriatum^{11,12} or by their effects on the canine renal artery¹³. Controversy exists, however, as to whether binding studies using labelled neuroleptics such as spiroperidol actually measure dopamine receptors. Our finding of an agonist-specific effect of GTP supports the conclusion that ³H-spiroperidol is binding to functional dopamine receptors in the caudate nucleus.

The binding of the potent dopamine receptor antagonist ³H-spiroperidol was studied *in vitro* using a direct filtration binding assay (see legend to Fig. 1a and refs 14-16). At 37°C ³H-spiroperidol bound to rat striatal membranes with an observed affinity of approximately 80 pM, reached equilibrium levels in 8 min, and had a half-time of dissociation of 20 min. Specific binding was defined as the difference between ³H-spiroperidol bound in the absence and presence of 2 μ M (+)butaclamol; this constituted 90-95% of total binding. At the same concentration, (-)butaclamol was inactive. GTP had no effect on the binding characteristics of ³H-spiroperidol. Scatchard analysis was consistent with the existence of only a single

class of high-affinity binding site. The presence of GTP did not lead to changes in either the K_d (78 ± 6 pM and 85 ± 5 pM in the absence, and presence of GTP, respectively; $n = 6$) or the density of binding sites for ^3H -spiroperidol (305 ± 1 fmol per mg and 306 ± 1 fmol per mg in the absence and presence of GTP, respectively). The control K_d value in this study was approximately fourfold lower than that reported previously^{14,15}. This is probably due to species differences—Creese *et al.* used bovine caudate¹⁴—and to the use of different tissues—Fields *et al.* used whole rat brain¹⁵.

The addition of GTP led to a decrease in the apparent affinity of dopamine for the ^3H -spiroperidol binding site ($\text{EC}_{50} = 0.003$ mM GTP). The effect of GTP on rat striatal membranes was maximal at the concentration used (0.3 mM GTP). At this high concentration the order of efficacy of purine nucleotides was as follows: $\text{GTP} = \text{GDP} > \text{ITP} \gg \text{GMP} = \text{guanosine} = \text{ATP} = \text{control}$ (Fig. 1a). These results are similar to the effects of purine nucleotides on β -adrenergic receptors⁷.

A variety of dopamine receptor agonists and antagonists effectively competed with ^3H -spiroperidol for binding sites on

Fig. 1 a, Effect of guanine nucleotides on the inhibition of ^3H -spiroperidol binding by dopamine in rat striatal membranes. Striatal membranes were isolated following homogenisation in 200 volumes of 0.32 M sucrose/10 mM Tris buffer (pH 7.5) by centrifugation at 20,000 g for 10 min at 4°C. Radioligand, drugs and nucleotides were dissolved in 2.8 mM ascorbic acid containing 10 μg per ml bovine serum albumin (BSA). An aliquot of the resuspended membranes (0.1 mg protein in 850 μl of 0.9% NaCl/10 mM Tris buffer, pH 7.5) were added to tubes containing 50 μl ^3H -spiroperidol (26 Ci mmol^{-1} ; 0.4 nM final concentration), 50 μl drug and 50 μl ascorbate/BSA or nucleotide (0.3 mM final concentration). Samples were incubated at 37°C for 10 min; the reaction was then terminated by the addition of 10 ml ice-cold buffered saline and samples were immediately filtered through type-AE glass fibre filters. Each filter was washed at room temperature with an additional 10 ml of buffered saline, and radioactivity was determined by liquid scintillation spectrometry in 7 ml of a Triton X-100/toluene-based fluor. The counting efficiency for tritium was approximately 32%. Points on the displacement curves represent the mean values of three independent determinations. In these experiments ^3H -spiroperidol binding ranged from 800 c.p.m., in the absence of dopamine, to 80 c.p.m., in the presence of 1 mM dopamine. Standard errors (not shown) ranged over 5–15%. ●, Control; ▲, GTP; □, GDP; ◇, GMP. b, The effect of 0.3 mM GTP on the inhibition of ^3H -spiroperidol binding by dopamine-receptor agonists and antagonists in rat striatal membranes. Methods used were identical to those described above. ●, α -flupenthixol; ○, α -flupenthixol + GTP; ▲, $(\pm)$ ADTN; △, $(\pm)$ ADTN + GTP; ■, epinine; □, epinine + GTP.

striatal membranes (Fig. 1b and Table 1). Addition of 0.3 mM GTP to the incubation medium did not affect the inhibition of ^3H -spiroperidol binding by the potent antagonist α -flupenthixol. In the presence of GTP, however, the agonists $(\pm)$ amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene (ADTN) and epinine were less potent in competing for ^3H -spiroperidol binding sites (Fig. 1b). Several dopamine-receptor agonists and the partial agonist apomorphine were less potent in displacing ^3H -spiroperidol binding in the presence of GTP, whereas antagonists were not affected by the presence of GTP (Table 1). The magnitude of the effect was independent of the potency of the agonist tested. Hill coefficients for the agonists/partial agonist were less than unity (0.49–0.61; Table 1) and increased only slightly on the addition of GTP (0.59–0.76). This finding differs from that with β -adrenergic receptors, in which GTP leads to a marked increase in the Hill coefficients for agonists towards unity. In the case of β -adrenergic receptors, Hill coefficients for antagonists are approximately 1.0 in either the presence or absence of GTP⁵.

It should be pointed out that the active isomers of the dopamine-receptor antagonists have Hill coefficients of approximately 0.65, whereas the inactive isomers have Hill coefficients of about 1.0 (Table 1). This difference suggests that the effect of the less active isomers is a reflection of their intrinsic activity and not of contamination with a small amount of the active isomers. It is likely that there are differences in the site or sites occupied by the active and inactive isomers. The Hill coefficients of the antagonists were not changed by the addition of GTP. Low Hill coefficients (<1) could indicate negative cooperativity between individual receptor sites or the existence of multiple binding sites, although it is not known whether either of these explanations is correct.

A possible explanation for the agonist-specific effect of GTP comes from studies of the binding of labelled agonists to glucagon receptors^{1,6}, β -adrenergic receptors⁸, prostaglandin E_1 receptors⁹ and opiate receptors¹⁰. In these systems, guanine nucleotides increase the rate of dissociation of agonists from their binding sites. Agonists, therefore, seem to be less potent in the presence of GTP. Labelled agonists for dopamine receptors have been used in direct binding studies^{17–19}. However, the specific binding of ^3H -dopamine to rat striatal membranes is usually only about 20% of total binding¹⁸. We have thus far been unable to examine the effects of GTP on ^3H -dopamine binding in the rat striatum.

Several reports have suggested that the action of GTP may be involved in the coupling of the receptor with adenylate cyclase^{1,5,20,21}. GTP is required for dopamine stimulation of adenylate cyclase in membranes prepared from homogenates of rat striatum^{2,4}. It is interesting that the hormonal sensitivity of striatal adenylate cyclase, uncoupled from its receptor by exposure to the venom of Russell's viper, was restored by the addition of GTP to the incubation medium²¹. The most direct evidence that the effect of GTP is related to the coupling of receptors with adenylate cyclase has come from studies of the β -adrenergic receptor–adenylate cyclase system in S49 lymphoma cells. In wild-type S49 cells, guanine nucleotides increase the K_d values and Hill coefficients for agonist, but not antagonist, inhibition of ^{125}I -iodohydroxybenzylpindolol binding²⁰. In contrast, S49 cells, in which the β -adrenergic receptor and adenylate cyclase are both present but 'uncoupled', lack an agonist-specific response to GTP. So far, only receptors that can be shown to be linked to adenylate cyclase have been reported to show decreased affinity for agonists in the presence of guanine nucleotides^{1,5–9}. Opiate receptors, which seem to be linked to adenylate cyclase in some systems²², have been reported to show nucleotide regulation of both agonist and antagonist binding¹⁰.

The relationship of neuroleptic binding sites to dopamine receptors has been questioned. The affinities of dopamine-receptor agonists and antagonists differ depending on whether they are determined in the presence of an agonist or antagonist ligand²³. Discrepancies also exist between the agonist and antagonist potencies determined by binding studies when

Assays were carried out as described in the legend to Fig. 1a. Each ratio of K_d values was calculated as the K_d in the presence of GTP to the K_d in the absence of GTP. The concentration of GTP was 0.3 mM. The results are expressed as the mean $\pm$ s.e.m. calculated from three to four independent determinations.

* Means values significantly different; Student's *t* test, $P < 0.05$.

compared with those determined in studies of dopamine-stimulated adenylate cyclase activity^{13,23}. Further, the subcellular distributions of ^3H -spiroperidol binding sites and adenylate cyclase in the rat brain are not identical²⁴. From such studies, it has been suggested that the dopamine receptor and adenylate cyclase are related but not identical sites. Also, decreases in dopamine-sensitive adenylate cyclase activity (85%) and ^3H -haloperidol binding (40%) occur following intrastriatal injection of kainic acid²⁵. The difference in the magnitude of the effects of kainic acid has led some investigators to question whether striatal adenylate cyclase and ^3H -haloperidol binding sites are associated. The data presented here demonstrate a specific effect of GTP on the inhibition of ^3H -spiroperidol binding by the same agonists which have previously been shown to activate adenylate cyclase^{11,12}. The connection between the striatal ^3H -spiroperidol binding site and the dopamine-sensitive adenylate cyclase is thus strengthened^{15,16}.

We thank Dr Kenneth P. Minneman for suggestions and discussions and Dr John McDermid, Wellcome, for ($\pm$)ADTN. N. R. Z. is a postdoctoral fellow of the USPHS (NS 05970). This work was supported by the USPHS (NS 09199, NS 13289 and AA 03537).

Mammary tumour virus and casein gene transcription during mouse mammary development

MORPHOGENESIS and differentiation of the murine mammary gland is dependent on the interaction of peptide and steroid hormones. These hormones cause mammary growth through proliferation of ductal and alveolar epithelial cells^{1,2} and differentiation of the gland for the production of the milk proteins, casein and α -lactalbumin^{3,4}. Mammary development frequently increases the incidence and results in an earlier onset of mammary tumours^{5,6}. The influence of mammary development upon tumorigenesis has been correlated with the appearance of mouse mammary tumour virus (MMTV) particles⁶⁻¹⁰. Importantly, the production of MMTV particles is dependent on alveolar differentiation and function^{7,11}. Lactating mammary glands from BALB/c mice contained considerably lower levels of MMTV RNA than glands from C3H mice infected with the milk-transmitted virus MMTV-S (ref. 12). In this study we have examined the influence of the hormonal changes that occur during mammary development on MMTV and casein expression by molecular hybridisation with specific complementary DNA (cDNA) probes to MMTV 70S RNA and casein 15S mRNA. Hence, the relationship between MMTV expression and the expression of a normal differentiated mammary function—the production of casein mRNA—was determined. We have quantitated MMTV RNA and casein mRNA in developing mammary tissues from BALB/c and BALB/c/c3H mice that have a low and high incidence of mammary tumours respectively^{6,13}. These studies demonstrate that the hormonal alterations occurring during mammary development enhanced MMTV RNA expression to a greater extent in the high than the low tumour-incidence strain, whereas similar changes in the level of casein mRNA were observed in both strains during mammary development.

A representative MMTV cDNA probe was synthesised *in vitro* by avian myeloblastosis virus reverse transcriptase using 70S MMTV RNA as template and calf thymus DNA fragments¹⁴ as a random primer^{15,16}. The level of MMTV RNA was quantitated in cellular RNA extracts by the titration method¹⁷. The amount of MMTV RNA, expressed as a percentage of the

Fig. 1 Detection of MMTV RNA and mouse casein 15S mRNA in mammary glands by molecular hybridisation. Cellular RNA was isolated by sodium dodecyl sulphate-phenol extraction with proteinase K digestion²⁰ followed by extraction with 3 M sodium acetate²¹. Hybridisations were carried out and assayed by S1 nuclease digestion¹⁹. *a*, Hybridisations of MMTVcDNA, equivalent Dot of 0.09, with MMTV 70S RNA isolated from purified MMTV virions ($\blacktriangle$) and RNA isolated from early pregnant ($\square$), late pregnant ($\blacksquare$) and late lactating ($\circ$) uniparous BALB/cfC3H mammary tissues. *b*, Hybridisations of mouse casein cDNA, equivalent Dot of 0.09, with purified mouse casein 15S mRNA ($\blacktriangle$) and RNA isolated from early ($\square$), mid ($\circ$) and late ($\blacksquare$) pregnant uniparous BALB/cfC3H mammary tissues.

cellular RNA, was determined by comparing the rate of hybridisation observed with each cellular RNA to the rate of hybridisation observed with purified 70S MMTV RNA (Fig. 1*a*). Casein mRNA was quantitated in the same manner (Fig. 1*b*) with a full-length cDNA probe synthesised from purified mouse casein 15S mRNA¹⁸ as described previously¹⁹. The limit of detection of MMTV RNA and casein mRNA was 0.0005% of the total cellular RNA.

Casein mRNA was quantitated in mammary tissues from virgin and uniparous BALB/c and BALB/cfC3H mice at various stages of mammary development. Figure 2*a* shows that the level of casein mRNA, which was at a very low level in the virgin gland (0.0009%), was present at an appreciable level in early pregnancy (0.0066%) and then increased to 0.365% of the RNA late in pregnancy. Casein mRNA increased nearly four-fold from late pregnancy to early lactation and was maintained at a high level, approximately 1% of the RNA, during lactation. Following weaning, casein mRNA decreased to one tenth or less of the lactating level, but was considerably higher than observed in the virgin gland. Essentially identical changes in the level of casein mRNA were observed during mammary development in both the low and the high mammary tumour incidence strains, BALB/c and BALB/cfC3H, respectively.

MMTV RNA was quantitated in mammary tissues from virgin and uniparous BALB/c and BALB/cfC3H mice at various stages of mammary development (Fig. 2*b*). The increased tumour incidence of BALB/cfC3H mice relative to the isogenic strain, BALB/c, is due to the milk-transmitted virus, MMTV-S, obtained by foster-nursing BALB/c mice on C3H. Note that normal BALB/c and BALB/cfC3H tissues contain 5–9 copies of MMTV DNA per diploid cell²². The level of MMTV RNA in the mammary tissues was below the limit of detection in virgin and early pregnant BALB/cfC3H mammary glands and was present at low levels (0.0014%) in mid pregnancy. MMTV RNA was at an appreciably higher level (0.0125%) in the

BALB/cfC3H mammary gland at late pregnancy and increased approximately twofold after parturition. Later in lactation, the level of MMTV RNA decreased from the level observed in early lactating BALB/cfC3H mammary glands. The decrease in MMTV RNA late in lactation may be due to the release of MMTV RNA particles into glandular secretions^{6–8,10,11}. MMTV RNA levels were similar in BALB/cfC3H mammary glands late in lactation and 10 days after weaning, 0.0076% and 0.0096%, respectively. Large variations in the amount of MMTV RNA (Fig. 2*b*) but not casein mRNA (Fig. 2*a*) were observed in pregnant and lactating BALB/cfC3H mammary tissues. Interestingly, differences in milk virus titre, particularly in uniparous mice, have been reported to be indicative of similar biological variation in virus production⁸. The level of MMTV RNA in BALB/c mammary tissues at all the developmental stages assayed was 0.0005% or less.

The hormonal changes that control normal mammary development also influence neoplastic development of the mammary gland^{5,6}. In BALB/c and BALB/cfC3H mice the mammary tumour incidence is higher in retired breeders than virgin mice (refs 6, 13 and D. Medina, personal communication). The occurrence of MMTV antigens in milk from lactating mice increases with the number of lactations in certain mouse strains^{9,10,23}. Mammary tumours from BALB/c and BALB/cfC3H retired breeders have higher levels of MMTV RNA than observed in uniparous lactating mammary glands (R. J. P. and S. H. S., in preparation). These observations suggest that additional cycles of hormonal stimulation during pregnancy and lactation may increase the level of MMTV RNA in mammary glands. Therefore, the level of MMTV RNA was quantitated in mammary glands from BALB/c and BALB/cfC3H lactating multiparous mice and retired breeders (Table 1). The levels of casein mRNA in multiparous lactating mice and retired

Fig. 2 Mouse casein 15S mRNA and MMTV RNA in mammary tissues during mammary development. Tissues were obtained from BALB/c and BALB/cfC3H virgin mice (Vi) and either pregnant (Pg), lactating (La) or post-weaning (PW) uniparous mice. Early (E), mid (M) and late (L) pregnant mice were staged at 1–7, 8–14, and 15–21 days of pregnancy, respectively. Early (E), mid (M) and late (L) lactating mice were staged at 1–7, 8–14 and 15–21 days of lactation respectively. Post-weaning mammary glands were obtained from uniparous mice 5 or 10 days following weaning. Cellular RNA was prepared and hybridisations were carried out as described in the legend to Fig. 1. The amount of casein mRNA (Fig. 2*a*) and MMTV RNA (Fig. 2*b*) are expressed as a percentage of the cellular RNA. Solid bars denote BALB/c tissues and cross-hatched bars denote BALB/cfC3H tissues, presented as the mean $\pm$ one s.e.m. for (*n*) determinations.

Table 1 MMTV RNA and casein mRNA in mammary tissue from multiparous mice and retired breeders

Strain	Developmental stage	MMTV RNA (% total RNA)	Casein mRNA (% total RNA)
BALB/cfC3H	Lactating-multiparous	0.0181	1.700
BALB/cfC3H	Retired breeder	0.0128	0.017
BALB/c	Lactating-multiparous	0.0006	1.790
BALB/c	Retired breeder	0.0009	0.014

Mammary tissue excised from 5–7 day lactating multiparous mice and retired breeders, obtained one month after weaning of the fourth litter, were used for the assays. Cellular RNA was prepared and hybridisations were performed as described in the legend to Fig. 1.

breeders of both strains were consistent with the developmental stage of the gland. In BALB/cfC3H mammary glands from multiparous lactating mice and retired breeders (Table 1), the level of MMTV RNA was similar to that observed in uniparous lactating, 0.0295%, and weaned, 0.0096%, mice. Mammary tissues from BALB/c retired breeders contained a low but detectable amount of MMTV RNA (0.0009%) whereas uniparous and multiparous BALB/c lactating mammary tissues contained lower levels of MMTV RNA ($\leq 0.0006\%$). Varmus *et al.*¹² also have reported that lactating BALB/c mammary glands contained low levels of MMTV RNA (0.0003%). Therefore, additional cycles of hormonal stimulation increased MMTV expression in BALB/c but not BALB/cfC3H mammary glands.

These studies indicate that the hormonal milieu required for mammary development and lactogenesis enhanced both casein and MMTV expression in the mammary gland of the high tumour incidence strain, BALB/cfC3H. Both MMTV RNA and casein mRNA were detectable by mid pregnancy and increased until the maximum level was observed early in lactation. Although the level of both MMTV RNA and casein mRNA decreased following weaning in both uniparous and multiparous mice, MMTV RNA did not decrease to the same degree as casein mRNA. Therefore, the accumulation of MMTV RNA in BALB/cfC3H mammary glands is dependent upon mammary development and influenced by differentiated mammary function. Consequently, the accumulation of B-type virus particles, which is dependent upon alveolar differentiation and function^{8,11}, is also related to and may be dependent upon accumulation of MMTV RNA in the mammary gland of high tumour incidence strains. Interestingly, an appreciable level of MMTV RNA was maintained in the absence of continued hormonal stimulation of the BALB/cfC3H gland. Casein expression in the low tumour incidence strain, BALB/c, was influenced similarly by the hormonal changes that occur during mammary development. However, MMTV expression during mammary development in BALB/c mice was not influenced to the same extent as observed in BALB/cfC3H mice. Therefore, MMTV expression in the low tumour incidence strain is apparently not influenced by hormonally-regulated mammary development to the same degree as in the high tumour incidence strain.

Genetic and biochemical evidence indicate that mouse strains contain different variants of MMTV^{6,24–28}. MMTV-O is apparently an endogenous virus transmitted as a germinal provirus in BALB/c mice^{24,25}, while BALB/cfC3H mice contain both MMTV-O and the exogenous virus, MMTV-S, transmitted by foster-nursing. Our studies indicated that MMTV-O and MMTV-S do not respond to the same extent to changes occurring in the hormonal environment during normal mammary development. Further studies using specific nucleic acid probes²⁶ or antibodies to type-specific antigenic determinants^{27,28} should provide additional evidence that MMTV-O and MMTV-S respond differently to changes in the hormonal environment during normal mammary development. The effect of mammary development on MMTV expression is related to

the tumour incidence of the strain, suggesting that multiple factors may influence MMTV expression during normal development.

This research was supported by contract NO1-CP-4-3385 within the NCI Virus Cancer Program. Purified MMTV virions and avian myeloblastosis virus reverse transcriptase were obtained through the Office of Resources and Logistics of the Virus Cancer Program. We thank Owen DeWitt for technical assistance and Dr Daniel Medina for providing the mice and reviewing the manuscript.

Male recombination is not induced in *Drosophila melanogaster* by extracts of strains with male recombination potential

NON-TRIVIAL frequencies of spontaneous male recombination in the hybrid progeny of *Drosophila melanogaster* males from so-called 'male recombination strains' and laboratory marker stock females are well documented^{1,2}. Attempts to induce male recombination by injection have produced conflicting results. The positive results originally claimed by Reddi *et al.*³ were not reproducible in two subsequent studies^{4,5}. Sochacka and Woodruff⁶ have suggested that the disparity in results may be attributable to the use of extracts from a male recombination strain in the former study only. They injected extracts from the male recombination strain OK1 (ref. 7) into laboratory marker strain females. These were crossed to the Canton-S strain, which lacks spontaneous male recombination potential, producing F₁ hybrids which yielded a low frequency of male recombination. Injection directly into F₁ hybrid males also yielded some recombinants. Similar tests using Canton-S as the source of the extract were negative. We describe here large-scale tests with different male recombination strains. We could not reproduce the injection effect of Sochacka and Woodruff, suggesting that their results may not be generally applicable. We suggest, furthermore, that the genetic implications of a negative injection result may be at least as interesting as those of a positive result. A positive result would imply the existence of some co-existing,

Table 1 Observed numbers of recombinants and the minimum number of recombination events in various studies

	Experimental		Total	Control		Total
	Recombinants	Minimum events		Recombinants	Minimum events	
	Actual			Actual		
Sydney	7	6	116,776	9	6	70,548
Brown	9	6	39,628	22	15	86,024
Sochacka and Woodruff ⁶	25	11	23,170	0	0	67,910

'Experimental' includes all cases of injections of extracts from male recombination strains into females and males.
'Control' includes injection with non-recombination strains, injection of solvents and no injection.

possibly non-essential, factor, such as a virus or episome. This would rule out explanations for male recombination based on incompatibility of genetic organisation in different strains. Explanations of this type, for example, in terms of spatial organisation of chromosomes⁸, have potentially important implications for normal nuclear organisation.

The experiments were carried out independently at Sydney University and at Brown University. Extracts from the strong male recombination strains, Harwich² and Hunter Valley⁸, were used in the experimental groups and extracts from the laboratory strain Canton-S were used as controls in both laboratories. In Sydney, Harwich or Hunter Valley extracts were injected into females of the laboratory strain *al cn bw* (chromosome II). At Brown, Harwich extracts were injected into the laboratory strains *al cl b c sp²* (chromosome II) and *rucuca* (chromosome III). The majority of control flies were injected with Canton-S extracts, a few were injected with Ringer's solution and a few were untreated. Experimental and control tubes were coded and combined for counting, an important consideration where low recombination frequencies are expected.

Altogether, 10 experiments were carried out. The initial experiments were made using the concentration of extract given by Sochacka and Woodruff⁶. Subsequently, concentrations up to four times higher were used. We also examined the effect of ageing the injected flies, in case a specific developmental stage or incubation period was important. In addition, following a suggestion by Dr D. Angus of Newcastle University, New South Wales, we injected extracts from various hybrids rather than from pure strains, on the grounds that male recombination might be attributable to an agent which multiplies preferentially in the hybrid.

None of the experiments showed an elevated level of recombination. Results have therefore been pooled within laboratories, and are presented in the first two lines of Table 1. We show both the actual number of recombinants found and the minimum number of independent recombination events⁹. Neither of these numbers is an entirely satisfactory measure of recombination intensity. The actual number of recombinants cannot validly be used in statistical tests if recombinants occur in clusters rather than independently of each other. On the other hand, comparisons based on the minimum number of recombination events are strictly valid only if a fixed number of progeny is screened per cross. In the present experiments, however, neither measure indicates an effect of the treatment.

The data of Sochacka and Woodruff⁶ are summarised in the third line of Table 1. The complete absence of recombinants in their control series is noteworthy considering that Canton-S was used by all three laboratories. It is a major cause of the significance of the difference in recombination frequency between their experimental and control groups. Also, the frequency in the experimental injected group is about an order of magnitude lower than the spontaneous frequency in OK1 hybrid males⁷.

There are, of course, several possible reasons for dissimilar results using different strain combinations. We suggest, nevertheless, that the hypothesis of direct transmissibility of male recombination by injection requires further substantiation.

Aphidicolin prevents mitotic cell division by interfering with the activity of DNA polymerase- α

THE study of the control of DNA synthesis would be helped if a variety of chemicals which influenced DNA synthesis in various ways was available. We have searched for chemicals which prevent mitotic division of sea urchin embryos, which requires DNA synthesis, but do not prevent meiotic divisions of starfish oocytes, which are independent of DNA synthesis¹. Aphidicolin² (I) is one such compound. Furthermore, recent experiments have shown that aphidicolin selectively inhibits the activity of DNA polymerase- α obtained from regenerating rat liver without interfering with the activity of DNA polymerase- β and mitochondrial DNA polymerase³. The function of the DNA polymerases in the complex process of DNA replication is not known. Correlative studies of DNA synthesis and the level of DNA polymerase activity suggest that DNA polymerase- α may be important in DNA replication⁴. However, in certain cases, DNA polymerase- β and - γ also increase at the time of DNA synthesis, and attempts to specify which of the DNA polymerases is 'replicative' or to assign roles to the various polymerases have not yet been successful⁴. We report here evidence that prevention of cell division by aphidicolin in sea urchin embryos is due to selective inhibition of DNA polymerase- α activity. This study implies a functional role for this polymerase activity during replication of DNA.

Fig. 1 Inhibition by aphidicolin of mitotic division of embryos of *Hemicentrotus pulcherrimus*. Five min after fertilisation, embryos were treated with various concentrations of aphidicolin. Morphological changes were observed for 150 min. Aphidicolin (insoluble in aqueous media) was dissolved in DMSO and then dispersed in seawater to give a DMSO concentration of 0.1% (v/v) in the solution, which did not affect cleavage.

When embryos of the sea urchin *Hemicentrotus pulcherrimus* were exposed to aphidicolin ($2 \mu\text{g ml}^{-1}$) for 150 min from 5 min after insemination, nearly all of them remained at the 1-cell stage whereas control embryos divided three times (Fig. 1). The incorporation of ^3H -thymidine into DNA of the embryos was inhibited by 90% by treatment with aphidicolin at $2 \mu\text{g ml}^{-1}$ (Table 1). The rate of protein synthesis was the same whether or not embryos were exposed to the compound (Table 1). RNA synthesis remains quite low during early cleavage and maternal messenger RNA synthesised during oogenesis and stored in eggs plays a central role in translation⁵. Therefore, the effect of aphidicolin on RNA synthesis was examined at the gastrula stage. The incorporation of ^{14}C -uridine into the acid-insoluble material was not affected by 1 h exposure to aphidicolin ($10 \mu\text{g ml}^{-1}$).

Aphidicolin ($40 \mu\text{g ml}^{-1}$) did not prevent 1-methyladenine-induced (45 ng ml^{-1}) meiotic maturational divisions in oocytes of the starfish *Asterias amurensis*⁶. Meiosis is a reduction in chromosome number and no chromosomal replication takes place during the maturational divisions. Thus, it seems that aphidicolin prevents the sequence of events necessary to complete chromosomal replication in sea urchin embryos rather than the process of karyokinesis and cytokinesis.

Inhibitors of deoxyribonucleotide biosynthesis such as *N*-hydroxyurea ($200 \mu\text{g ml}^{-1}$) and 5-fluorouracil ($200 \mu\text{g ml}^{-1}$) did not affect the first cleavage of sea urchin embryos. In fact,

Table 1 Effects of aphidicolin on DNA and protein synthesis in embryos of *Hemicentrotus pulcherrimus*

Aphidicolin concentration ($\mu\text{g ml}^{-1}$)	^3H -Thymidine incorporation (%)	^3H -L-Leucine incorporation (%)
0	100	100
0.02	76	105
0.2	38	125
2	10	124
10	5	110

Five min after fertilisation, ^3H -thymidine ($0.63 \mu\text{Ci}$; 24 Ci mmol^{-1}) and various amounts of aphidicolin were added to 5×10^5 eggs in 5 ml of seawater. Ninety min later, embryos were sedimented, washed, fixed and extracted with 1 M perchloric acid, and the acid-insoluble radioactivity was counted according to the method of Hinegardner *et al.*⁷. The radioactivity in the control experiment was 1.7×10^4 c.p.m. ^3H -L-Leucine (0.2 mCi ; 58 Ci mmol^{-1}) was added to 4×10^5 unfertilised eggs suspended in 20 ml of seawater. Five min later, eggs were thoroughly washed with seawater, suspended in 20 ml of seawater, inseminated and various amounts of aphidicolin were added to 2.5-ml aliquots of the suspension. Ninety min later, embryos were collected, fixed and extracted with 10% TCA at 90°C , and the acid-insoluble radioactivity was counted according to the method of Mano⁸. The control value was 5.9×10^3 c.p.m. Aphidicolin was dissolved in DMSO and then dispersed in seawater to give a final concentration of 0.1% DMSO (v/v), which did not affect DNA or protein synthesis in the embryo.

Table 2 Effects of aphidicolin on activity of DNA polymerase- α , - β and - γ obtained from the nuclear fraction of blastulae of *Hemicentrotus pulcherrimus*

Aphidicolin concentration ($\mu\text{g ml}^{-1}$)	DNA polymerase activity (%)		
	α	β	γ
0	100	100	100
0.5	39	—	—
2	10	102	95
10	0	99	98

DNA polymerase- α was purified from the nuclear extract using phase separation and hydroxyapatite and phosphocellulose columns. The properties of the polymerase were similar to those described by Loeb¹⁰. DNA polymerase- β was obtained as described elsewhere¹¹. The activated DNA-dependent DNA synthesis with DNA polymerase- α and - β were determined using 50 mM Tris-maleate buffer, pH 8.5, as described previously¹¹. The poly(rA)-oligo(dT)₁₂₋₁₈ dependent DNA polymerase- β and - γ activities were measured as described elsewhere (Habara, A.; Nagano, H. & Mano, Y., in preparation). In the case of DNA polymerase- β , the values shown in this table were obtained by using activated DNA as template primer. The poly(rA)-oligo(dT)₁₂₋₁₈ dependent DNA polymerase- β activity was also insensitive to aphidicolin. The activity of DNA polymerase- α , - β and - γ in the absence of aphidicolin was 3,200, 600 and 5,200 c.p.m., respectively. Aphidicolin was dissolved in DMSO and then dispersed in the reaction mixtures to give a final DMSO concentration of less than 0.1% (v/v). At these concentrations, DMSO did not affect the activity of the DNA polymerases.

unfertilised sea urchin eggs have enough pools of four deoxyribonucleoside triphosphates to support two or three cycles of DNA replication⁷. This excludes the possibility that aphidicolin acts by inhibiting deoxyribonucleotide biosynthesis, thereby depriving DNA polymerases of necessary substrates.

The effects of aphidicolin on the activity of DNA polymerase- α , - β and - γ obtained from the nuclear fraction of the sea urchin embryos (blastulae) were next examined. The addition of aphidicolin ($2 \mu\text{g ml}^{-1}$) inhibited the activity of DNA polymerase- α by 90% whereas that of DNA polymerase- β and - γ was not affected by the treatment (Table 2). Thus the degree of inhibition by aphidicolin of the activity of DNA polymerase- α was nearly the same as that observed for cleavage and DNA synthesis in the intact cell (Fig. 1, Tables 1 and 2). However, it was observed that a higher dose of aphidicolin was required to inhibit the activity of DNA polymerase- α which was further purified by a DEAE-Sephadex A-50 column; aphidicolin at $2 \mu\text{g ml}^{-1}$ produced 58% inhibition of DNA synthesis with this preparation. This could be due to a change in the enzyme molecule from its native state during purification or could be related to the adherence of some component to the enzyme which facilitates the action of the drug and is separated from the enzyme by DEAE-Sephadex chromatography. We are at present carrying out further studies designed to test these possibilities. Similarly, aphidicolin inhibited the activity of DNA polymerase- α obtained from unfertilised eggs but did not affect DNA polymerase- β activity. These results suggest that DNA polymerase- α plays an essential part in chromosomal DNA replication in cleavage of sea urchin embryos. Thus aphidicolin has considerable potential for investigating the fundamental nature of the cell functions concerned.

We thank A. Habara for a supply of DNA polymerase- γ . This work was partly supported by a grant from the Ministry of Education, Science and Culture, Japan.

Resistance to viomycin conferred by RNA of either ribosomal subunit

THE basic peptide antibiotic viomycin inhibits prokaryotic protein biosynthesis^{1,2}, and seems to bind at least to the small ribosomal subunit because it competes partially with the binding of streptomycin³. However, viomycin does not induce misreading like streptomycin¹, but promotes association of the ribosomal subunits, stabilises 70S couples⁴, and blocks translocation^{5,6}. Interestingly, resistant mutants have been found containing either an altered 30S or an altered 50S subunit^{7–9}. Viomycin strengthens the association of the sensitive subunits but does not affect the association of subunits derived from resistant mutants⁴. These mutants have been obtained from *Mycobacterium smegmatis*, which is highly sensitive in culture in contrast to *Escherichia coli*. We describe here the formation of totally reconstituted subunits using components of sensitive and resistant ribosomes. The reconstituted particles were tested with their complementary, sensitive subunit with respect to viomycin-induced 70S couple formation. The resistance property of either subunit was shown to be located in the RNA moiety.

In the first series of experiments two Rabinowitchi (R) strains of *M. smegmatis* were used: R15 as the viomycin sensitive parental strain and the resistant mutant R33 which has an altered 30S subunit⁹. Intact 16S RNA from 30S subunits of both strains was isolated by the phenol method¹⁰. The isolation of the total proteins (TP30) and the reconstitution procedure for the small subunit have been reported¹¹. RNA and protein moieties from the sensitive and resistant strains were reconstituted in all combinations. The reconstituted particles were supplemented with sensitive 50S (R15) subunits and analysed on sucrose gradients. The conditions of the sucrose gradient centrifugation were chosen so that sensitive ribosomes only formed appreciable amounts of 70S couples in the presence of the drug⁴. Thus, when the ribosomal component conferring the resistance was used for reconstitution, viomycin should not be able to induce the formation of 70S couples.

Figure 1 shows the results. The homologous reconstitutions behaved as expected. 30S particles reconstituted with components of the sensitive strain form 70S couples in the presence of viomycin (Fig. 1b), whereas those obtained with resistant components do not (Fig. 1d). The heterologous reconstitution shows a sensitive response (70S couple formation) when parental 16S RNA was used (Fig. 1f). In contrast, a resistant response was found in the case where mutant 16S RNA was reconstituted with parental TP30. Thus, the resistance

follows the 16S RNA and is not related to the protein moiety (TP30). We conclude that the resistance of the strain R33, which has an altered 30S subunit, is conferred by the 16S RNA.

A similar analysis was performed with native, sensitive 30S subunits and reconstituted 50S particles. 50S subunits were obtained from R15 as the sensitive strain and from the resistant mutant R31 which has an altered 50S subunit⁹. The procedures for the isolation of (23S + 5S) RNA and total proteins (TP50)

Fig. 1 Sedimentation profiles of reconstituted 30S particles and wild-type 50S subunits in the presence and absence of viomycin. In the insets the ribosomal components are listed which were used for reconstitution of the 30S particle: where not indicated as R33 the 16S RNA (16S) and the proteins (TP30) were derived from 30S subunits of the sensitive parental strain R15. Cells were grown and 70S ribosomes prepared as described previously⁷. To remove attached RNase, ribosomes were washed with a buffer containing 10 mM Tris-HCl, pH 7.5, 0.5 M LiCl and 10 mM Mg acetate (ref. 10). The isolation of subunits and RNA (from the subunits which contain intact RNA) was as described¹⁰, the preparation of total proteins TP30 followed ref. 11. For total reconstitution of 30S particles 2.5 A_{260} units of 16S RNA and 0.4 A_{230} units of TP30 in 20 mM Tris-HCl (pH 7.6), 400 mM NH_4Cl , 20 mM Mg acetate, 0.2 mM EDTA and 2 mM β -mercaptoethanol were incubated in 100 μl at 40° for 20 min. One A_{260} unit of reconstituted 30S particles were mixed with 0.4 A_{260} units of parental 50S subunits in a buffer containing 10 mM Tris-HCl, 4 mM Mg acetate and 60 mM NH_4Cl , and where indicated 15 μM viomycin. The mixture was incubated for 10 min at 37° and loaded on a sucrose gradient (10–30%) with the same ionic conditions and where indicated with 15 μM viomycin. After centrifugation for 19 h at 17,000 r.p.m. and 4°C in a Beckman SW40 rotor the gradients were automatically monitored for A_{260} .

Fig. 2 Sedimentation profiles of wild type 30S subunits and reconstituted 50S particles in the presence and absence of viomycin. Where not indicated as R31 the (23S+5S) RNA (RNA) and the total proteins (TP50) were derived from 50S subunits of the sensitive parental strain R15. Isolation of subunits and RNA was as described in Fig. 1, the preparation of TP50 followed ref. 10. For total reconstitution of 50S particles 2.5 A_{260} units of (23S+5S) RNA and 0.4 A_{260} units of TP50 were incubated in the conditions of the two-step incubation¹⁰. Parental 30S subunits (0.6 A_{260} units) were mixed with 0.4 A_{260} units of reconstituted 50S particles, incubated and analysed on sucrose gradients as described in Fig. 1.

and for the reconstitution of the large subunit have been described¹⁰. Both homologous and heterologous reconstitutions led to particles sedimenting at the 50S position (Fig. 2). In the presence of viomycin we found a pattern equivalent to that shown for reconstituted 30S particles in Fig. 1: All reconstituted 50S particles containing parental RNA react as sensitive particles (70S couple formation, Fig. 2b, f), whereas those containing mutant RNA behave as resistant particles (no 70S couple formation, Fig. 2d, h). We conclude that the resistance of strain R31 which has an altered 50S subunit is also conferred by the RNA moiety of the large subunit.

Both reconstituted 30S and reconstituted 50S particles containing mutant 16S and (23+5S) RNA, respectively, could form 70S couples with their complementary native subunits only in the presence of higher Mg^{2+} concentration (above 12–15 mM; data not shown). In spite of their normal sedimentation and association behaviour the reconstituted particles were only poorly active in *in vitro* systems of protein synthesis.

Viomycin is the fourth example where resistance against an antibiotic is located in the RNA. Kasugamycin-resistant ribo-

somes contain an altered 16S RNA; the RNA is under-methylated near the 3' end¹². Erythromycin resistance can be due to an over-methylated 23S RNA¹³. Recently, a thiostrepton producing organism was described which protects itself against this drug by methylating the RNA from the large ribosomal subunit¹⁴. However, viomycin is the only case so far known in which the resistance against the drug can be located in the RNA moiety of either the small or the large subunit. Taken together with our observation that viomycin induces association these findings suggest that the RNA of both subunits is involved in the association reaction.

We thank Drs H. Teraoka and Dr. R. Brimscombe for discussions. This work was supported in part by a grant to T.Y. from the Ministry of Education of Japan.

Corrigendum

In the letter 'Visual response in barnacle photoreceptors is not initiated by transitions to and from metarhodopsin' by Z. Atzmon, P. Hillman and S. Hochstein, *Nature* 274, 76 (1978), the words 'blue' and 'red' heading the third and fourth columns of Table 1 should be interchanged.

Nature Index and Binders

The complete **Index** for 1977 is available, price £2.50 (U.K.), US\$5.00 (Rest of World). Copies of the 1976 index are still on sale, prices as above.

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

matters arising

Relative merits of 'extreme-pressure' additives

THE relative merits of 'extreme-pressure' additives are best examined under comparable conditions of 'mild wear' when only a fine dust is abraded from the rubbing surfaces and no macroscopic damage has been done. Macroscopic damage always leads to 'catastrophic' conditions and must therefore be avoided to ensure safe operation for a practically indefinite period. The criterion for safe operation is the validity of Amontons' law. The principal function of any extreme-pressure additive is to extend substantially the range of normal loads in which one can be certain that only mild wear will take place, so that bearing pressures of at least $15,000 \text{ kg wt cm}^{-2}$ are maintained. An optimum concentration¹ exists for each extreme-pressure additive which can react with the lubricated surfaces. Any comparison of extreme-pressure additives must therefore be made at their optimum concentrations and at normal loads for which Amontons' law is obeyed. With 0.9255-cm diameter En-31 steel balls in a four-ball apparatus running at 1,500 r.p.m. the optimum concentrations of two different chlorinated paraffin waxes and of benzyl chloride in a light mineral oil were respectively 5, 2 and 1% by weight, corresponding to 59, 29 and 8 mg-atoms of chlorine per 100 g of oil².

The existence of an optimum concentration suggests that two counteracting processes are responsible for the action of extreme-pressure additives. It is difficult to see how the formation of a protective coating on its own could account for an optimum concentration, but the view expressed recently by McCarroll *et al.*³ that extreme-pressure lubricants containing either sulphur or chlorine form with steel "surface layers of iron sulphide or chloride which prevent metal wear and seizure" is quite unacceptable, because mild wear always takes place, even if the wear prints have a mirror finish. What the extreme-pressure additive does to extend the range of validity of Amontons' law of its base oil, is to lower both the force of friction and the rate of wear which would be encountered with the base oil. At their optimum concentrations each of the chlorine-containing additives mentioned above reduced the coefficient of friction of the base oil by 15%, from 0.100 to 0.085, and extended the range of validity of Amontons' law from 16.5 kg wt to respectively 34, 32 and 26 kg wt (Fig. 1).

Fig. 1 Force of friction-normal load diagrams (0.9255 cm diameter En-31 steel balls; 1,500 r.p.m.; 30 s runs; additive solutions of optimum concentrations). $\times$, Light mineral oil; $\square$, 5% by wt chlorinated paraffin wax A; $\triangle$, 2% by wt chlorinated paraffin wax B; $\circ$, 1% by wt benzyl chloride (% solutions in light mineral oil).

On this evidence benzyl chloride was less effective than either of the two chlorinated paraffin waxes. The same order of merit was just discernible from the wear scar diameter curves. At 21.6 kg wt for instance, the respective diameters for 30 s runs were 0.330, 0.325, and 0.323 mm. [The bearing pressure of $25,251 \text{ kg wt cm}^{-2}$ at the end of each of these runs was still well within the extreme-pressure range whereas McCarroll and his colleagues had worked so far outside the range of validity of Amontons' law that macroscopic damage had been done and their pressures had fallen to $4,296 \text{ kg wt cm}^{-2}$ and less. Their rate of wear had been nearly 400 times larger than ours.] The corresponding volumes of dust abraded were 1.21×10^{-7} , 1.14×10^{-7} , and $1.11 \times 10^{-7} \text{ cm}^3$. By electron beam induced X-ray analysis considerably

less chlorine was found on wear prints obtained with 1% of benzyl chloride than with the optimum concentration of one of the chlorinated paraffin waxes (Table 1). Wear prints obtained with the base oil alone in the transition region from 'mild' to 'catastrophic wear' (Fig. 2a) resembled those found earlier by Czichos and Kirschke⁴. They had the appearance of a paste having been smeared over the wear print. By contrast, scanning electron micrographs from runs with chlorinated paraffin wax (Fig. 2b) and benzyl chloride (Fig. 2c) in conditions of mild wear showed clearly defined details of the wear scar areas. A striking difference between them was some wear debris sticking to the wear prints obtained with chlorinated paraffin wax (Fig. 2b). These blobs of debris contained more chlorine than the areas around them (Table 1).

Fig. 2 a, SEM photomicrograph ($\times 28,000$) of a wear print on an En-31 steel ball after a 30 s run with a light mineral oil at 15.7 kg wt and 1,500 r.p.m. b, A wear print on an En-31 steel ball after a 30 s run with the optimum concentration (2% by wt) of chlorinated paraffin wax at 21.6 kg wt and 1,500 r.p.m. Blobs of wear debris can be seen on the wear scar. ($\times 2,500$). c, A wear print on an En-31 steel ball after a 30 s run with the optimum concentration (1% by wt) of benzyl chloride at 21.6 kg wt and 1,500 r.p.m. ($\times 2,700$).

Table 1 Chlorine content found by electron beam induced X-ray analysis of the bases that the contents of Mn, Cr, Fe, and Cl add up to 99.99%

Extreme-pressure additive	Percentage of Cl		
	On wear print area	On blobs of debris	On arbitrarily selected spots
5% by wt chlorinated paraffin wax B	0.38	2.48	—
2% by wt chlorinated paraffin wax B (optimum concentration)	0.20	1.34	—
1% by wt benzyl chloride (optimum concentration)	Trace	—	0.10

Wear prints were obtained from 30 s runs with 0.9525-cm diameter En-31 steel balls at 1,500 r.p.m. and 21.6 kg wt.

We conclude from these observations that chlorinated paraffin wax is superior to benzyl chloride as an extreme-pressure additive. While the chemical reactivity of the additive plays some part in the mechanism of extreme-pressure lubrication, it does not lead to the formation of a wear-protective layer.

ROBERT SCHNURMANN
TALAL M. C. PORTER

- Czechos, H. & Kirschke, K. *Wear* **22**, 321 (1972)

SILVER AND MOULD REPLY—We were rather surprised that Schnurmann and Porter found "quite unacceptable" our view¹ that extreme pressure lubricants containing either sulphur or chlorine form with steel surface layers of iron sulphide or chloride which reduce metal wear and prevent seizure. This is not only our view but also that given by Rowe², Prutton³, Davey⁴ and many other workers in the field of extreme pressure lubrication. We were similarly surprised to read the statement that the chemical reactivity of the additive, although playing some part in the mechanism of extreme pressure lubrication, does not lead to the formation of a wear-protective layer. This too is in contrast with our findings³, and the findings of others^{6,7}, of the relationship between chemical activity and extreme pressure performance.

However, it is possible that a misunderstanding has arisen over the definition of the lubrication condition known as 'extreme pressure'. By this we, and others, mean the conditions whereby lubrication is maintained by means of a surface layer of principally inorganic material. These

conditions are operable under the severe loadings found in hypoid gears or in certain metal cutting operations, and are in contrast with those used by Schnurmann and Porter in their experiments. In lower loaded anti-wear tests⁸, we found that chlorinated hydrocarbons gave a slightly better performance than benzyl chloride, although at the same chlorine concentration in each oil; however, we must question the validity of results obtained from blends of chlorine compounds as described by Schnurmann and Porter, each with such different chlorine contents.

Interspecific competition in tits

DHONDT has recently made a case for the existence of interspecific competition between blue and great tits¹. My first criticism is mainly statistical and concerns Dhondt's Fig. 3 in which he presents a Lotka-Volterra graph with the equilibrium lines for the two species, estimated subjectively by eight colleagues. I tried a discriminate function analysis as a more rigorous approach and found that the blue tit line had a slight, though insignificant, positive slope. Moreover, in a linear multiple regression of population change of one species on the density of both species, neither species had a significant effect on the other. Consequently, neither the competition coefficients nor the conclusions about niche breadth drawn from the coefficients can be upheld.

My second criticism concerns the interpretation of the significant regressions in Dhondt's Figs 1 and 2. Both figures show that relative to great tits, the reproductive success of blue tits increases as the combined density of the two species increases. Because of the greater variance of the great tit density the result, especially in Fig. 2, could be due to intraspecific, density-dependent effects. In a linear multiple regression of relative competitive ability (great tit fledged per pair divided by blue tit fledged per pair) on year, blue tit density, great tit density, and the ratio of

great tit density to blue tit density, no one independent variable is significant although the whole regression is significant. Thus, the dependence of relative competitive ability on combined density seems uncertain and the possible contribution of the blue tit–great tit ratio should not be rejected. Finally, as there will be interspecific differential mortality, emigration, and so on, there is no reason to think that the equilibrium combined density should be where the reproductive abilities of the two species are equal.

British data support the trends reported by Dhondt except that in contrast to Dhondt's study, there is a strong positive correlation between changes in blue and great tit densities².

I thank M. G. Bulmer, J. R. Krebs, and C. M. Perrins for useful discussions.

EDWARD O. MINOT

Edward Grey Institute,
Department of Zoology,
Oxford, UK

- Dhondt, A. *Nature* **268**, 521–523 (1977)
- Minot, E. O. (in preparation)

DHONDT REPLIES—In my letter¹ I did two things (1) demonstrate that competition for food in the breeding season between great and blue tit results in a reduced fitness (fewer young produced) and (2) speculate how these titmice nevertheless coexist. Minot confirms point (1) but here criticises point (2).

The first part of Minot's criticism concerns the isoclines I tried to estimate. The method I used was unorthodox. I thought that fitting the lines by eye made it possible to correct for aberrant points caused by varying environmental factors. The more orthodox approach is to calculate a multiple regression equation in which the relative change in numbers (not the absolute value as Minot has done) is expressed as a function of each species' density. Doing this, leaving the 1962 point out (see ref. 1), results in isoclines very similar to the ones drawn in my Fig. 3. These are, for the great tit (GT) $1.817 - 0.075 \text{ GT} - 0.045 \text{ BT} = 0$ and for the blue tit (BT) $1.186 - 0.098 \text{ BT} - 0.0087 \text{ GT} = 0$. It is correct that change in numbers of either species is not significantly correlated with the density of the other species. However both partial correlation coefficients are negative and the one expressing the effect of the BT on GT change in numbers is almost significant ($r = -0.42$, $t_{14} = 1.736$, $P = 0.05$, one tailed), although the other one is much lower ($r = -0.23$). We know however, that the key factor, contributing most of the variance to annual mortality is 'overwinter mortality'^{2,3}. Therefore it would be surprising if change in numbers could be related directly to breeding density in the previous year, without correcting for the factors that cause this variance. I conclude

therefore that the competition coefficients should be treated cautiously but need not be rejected. The conclusions about niche breadth were not, as Minot states, derived from the competition coefficients, but inferred from the results in my Table 1, and only refer to the breeding season. I did not imply that, at other times of the year, this situation holds.

In the second part of his criticism Minot concludes that, because BT breeding numbers vary less than GT numbers, there could be a contribution of the relative proportion of each species to relative competitive ability. This may be so at high combined densities, but using only the data where the variance of the two species is not different (my low combined density years, upper line in Fig. 1) my conclusion is not affected.

I am grateful to Minot for pointing out the difficulty of this type of a posteriori data analysis. I think that critical field experiments designed to test hypotheses will contribute more to our understanding of this problem than further manipulation of the data. The first results from such experiments^{4,5} show that outside the breeding season great and blue tit also compete strongly, but that the situation is reversed and that the blue tit is more affected by it than the great tit.

Cordilleran Benioff Zones

CONEY AND REYNOLDS¹ have interpreted the radiometrically dated igneous rock pattern in the southwestern boundary of North America in terms of the evolution of a convergent plate margin. They conclude that the pattern reflects a progressive decreasing of the Benioff Zone dip angle from about 130–110 Myr to about 55–40 Myr ago and a rapid increasing of dip from about 40 to 15 Myr. Because of these changes in dip, the magmatic arc zone was displaced about 1,000 km inboard from the convergent margin until 55–40 Myr, then swept it back towards the trench by about 20 Myr. The width of this magmatic zone also changes as a function of the dip angle, from narrow at steep angles to very wide at low angles. Although the data seem to be consistent in supporting their interpretation, another interpretation based on the application of the same plate tectonic scheme^{2–5} used by Coney and Reynolds can be proposed.

According to the model of Dickinson and Hatherton^{2–5}, the surface arc mag-

Fig. 1 Growth of the magmatic arc zone. The time when the descending plate approximately reached the 300 km limit of the low-velocity layer is indicated by the arrow.

matism occurs above the zone in which the descending plate intersects the low-velocity layer of the upper mantle. This zone extends from a depth of about 100–300 km. By extrapolating this concept to the earlier stages of development of a magmatic arc, it can be expected that the width of the surface manifestation zone increases as the descending plate reaches greater depths within the low-velocity layer. When the plate reaches the 300 km-limit, if no changes in dip occur, the width of the magmatic arc zone remains nearly constant, until the subduction process ends and the geometry changes. In respect of the zone between 0 and 100 km depth, called the zone of shallow earthquakes, the dip can be different compared to the dip in the low-velocity zone as a consequence of the differences in properties and factors which control the plate interactions in the margin. Thus we can expect two dip angle zones⁶, which have been recognised in several parts^{2–6} and different dip changes in time. At the earlier stages the dip is steep and decreases as the margin evolves until the subduction process finishes or the geometry changes.

Fig. 2 Magmatic production zone dip angle as a function of time beneath southwestern North America.

By examining the data of Coney and Reynolds, we find that the width of the magmatic zone increases from about 130 to about 70 Myr and remains nearly

constant between 70 and 20 Myr with certain changes from 30 to 20 Myr (Fig. 1). By using a limits of 100 to 300 km for the low-velocity layer and the width of the magmatic arc zone, we can calculate the magmatic production zone dip angle, which is nearly constant from 70 to 20 Myr (Fig. 2). In respect of the zone of shallow earthquakes, the dip angle in this zone experiences a progressive flattening from 130 to about 70–60 Myr, remains constant between 70–60 and 30 Myr, followed by a rapid steepening from 30 to 15 Myr (Fig. 3).

Fig. 3 Shallow earthquakes zone dip angle as a function of time beneath southwestern North America.

The subduction rate during the earlier stages of development can be easily estimated from Fig. 1. The rate increases from 130 to 70 Myr. The changes in the interval between 30 and 20 Myr could represent the evolution of the Kula-Farallon triple junction as suggested in the reconstruction of Atwater⁷. Thus, these changes can be explained as the result of cessation of subduction caused by the change in plates geometry.

It is expected that the model sketched here represents a more reliable approach to understanding the evolution of the southwestern margin of North America. The qualitative aspects of this model were already included in a work under preparation which includes studies of the metallogeny zoning in northwestern Mexico and the evolution of Baja California peninsula. Further details of the present discussion will also be reported elsewhere.

THE DRUGS HANDBOOK

Paul Turner and Glyn Volans

A dictionary of drugs, arranged in alphabetical order of their medically approved names, with a trade names index. Each entry gives a brief description of the actions, uses and adverse effects of each drug — the sort of information that has been almost unavailable in the non-specialist area of pharmacology until now. Moreover, the book is presented in a concise handbook format to fit easily into a briefcase or capacious pocket. It should prove invaluable to anyone involved in the medical use of drugs.

'Concise, accurate and up-to-date' — *Miss W. E. Hector, Senior Lecturer, Queen Elizabeth College, London.*

*UK Price hardcover £4.95, 0 333 21612 1,
paperback £1.95, 0 333 23655 6.*

Please order through your local bookseller or in case of difficulty write to The Macmillan Press Ltd., Little Essex Street, London WC2R 3LF.

Our energy alternatives

Walt Patterson

Earth, Water, Wind and Sun: Our Energy Alternatives. By D. S. Halacy Jr. Pp. 186. (Harper and Row, New York and London, 1978) £4.95.

Too many commentaries on 'alternative energy' seem to assume that we have only just discovered the sun. What is needed is a sense of historical perspective. It is otherwise too easy to overlook the fact that many ingenious technologies to exploit ambient energy flows like wind and sunlight were developed decades, indeed centuries ago. The principles and even the engineering of such technologies are often better understood than those of so-called 'conventional' energy technologies like offshore oil extraction or nuclear power. This historical perspective is one of several distinctive virtues displayed in D. S. Halacy's book, an outstanding example of an under-rated discipline and popular science writing at its best.

Even for a battle-weary reader case-hardened by continual exposure to outpourings about 'alternative energy', Halacy's book has an exhilarating freshness, and is quite unexpectedly absorbing, partly because of the frequently unfamiliar and fascinating detail included and partly because of the writing itself. The book sustains the reader's interest without gimmicks or gee-whizzery, succumbing neither to the breathless flashiness prevalent in the 1950s nor to the more recently fashionable monitory breast-beating and finger-pointing. Furthermore, Halacy reveals himself to be a virtuoso of the short sentence. His prose races along, delivering an astonishing quantity of information accurately and effortlessly, without a hint of condescension.

He sets the stage with an introductory chapter entitled "The Energy Crisis Is Real", or, as he puts it, "But first, the bad news." It would doubtless be possible to quarrel with the picture he paints, at least in some particulars. He is preoccupied almost entirely with energy supply, and discounts far too completely the opportunities for improved efficiency—for optimising the balance between ambient energy, fuel energy, energy conversion systems, and desired end-use objectives. However, he then moves on to devote

chapters to geothermal energy, water-power, tidal power, sea thermal energy, wind, biofuels, and solar energy; and in each case his survey is both crisply concise and impressively comprehensive. He discusses basic principles, pioneering projects, current plans, proposals and prospects for the future, salting the discussion with striking examples and vivid turns of phrase. You probably know about Palmer Putnam's huge windmill on Grandpa's Knob; but did you know about Georges Claude's sea thermal plant with the intake pipe one and one quarter miles long, off the Cuban coast? In 1927? Or consider this thought-provoking aside, on the theoretical limit to recovery of energy from the wind: "(Extracting all the energy would mean bringing all the wind to a dead stop, an interesting possibility.)".

Halacy also avoids a pitfall into which many of his compatriots topple.

Unlike them he does not seem to believe that energy issues stop at the three-mile limit around the US. On the contrary he draws his examples and his ideas from every corner of the globe, although activities in the US do tend to predominate.

The book also offers a wealth of pictorial accompaniment to the text, including some photos of considerable rarity value.

All told, in 186 pages Halacy has put together a book which can be recommended with enthusiasm as one of the best available introductions to "our energy alternatives". Even its upbeat final sentence is welcome: "It's our move—and the prospects are encouraging." The next time some official spokesman threatens you with freezing in the dark, introduce him to Halacy.

Walt Patterson is energy consultant to Friends of the Earth (London) Ltd.

Ecology of freshwater macrophytes

River Plants: The Macrophytic Vegetation of Watercourses. By S. M. Haslam. Pp. 396. (Cambridge University Press: Cambridge and London, 1978) £27.50.

AGNES ARBER published her outstanding book on water plants nearly 60 years ago. Apart from Fritz Gessner's *Hydrobotanik*, Dr Haslam's is the first dealing with these plants, and based on original research, to have appeared since then. A causal analysis of the distribution of river plants throughout Britain is attempted in terms of flow, substrate and nutrients. These findings are applied to downstream changes in habitat and species composition in whole rivers. This leads to a classification of the vegetation of streams on soft rocks, streams on hard rocks and, finally, of channels with little flow. A preliminary account follows of the vegetation of watercourses in eastern North America and the book concludes with five chapters on applied aspects—uses and hazards created by river plants, their management and their relationship to pollution.

The author clearly intends to interest and indeed educate non-botanists and particularly those engaged in water

planning and management; there is an initial set of drawings of 'field' plants, and symbols are used in text, tables and river maps for the commonest species. Perhaps this explains the way degrees of correlation between nutrient and species distribution are presented (Tables 8.2, 8.6) and the grouping of all moss data as 'mosses'. The professional biologist or teacher may find it difficult to extract succinct information because of inevitable compression of data and, sometimes, insufficient distinction between generalisations based on these data and on subjective assessment. The book is very well produced, with good illustrations, pleasant lay-out and few errors—the most serious being the omission of all data from Fig. 6.12. These minor faults only slightly mar an outstanding, single-handed contribution to river biology—the first classification in terms of their macrophytes of British (and some North American) watercourses. The book can confidently be recommended to all those interested in the ecology of freshwaters.

D. H. N. Spence is Professor and Head of the Department of Botany at the University of St Andrews, UK.

Origins of senescence

The Genetics of Aging. Edited by E. L. Schneider. Pp.424. (Plenum: New York and London, 1978.) \$39.

DESPITE a considerable amount of research in recent years, as one of the contributors to this volume states, "... a universally acceptable definition of normal biological aging is still not available. The origins of senescence remain enigmatic, and little agreement exists regarding its true nature". Having read this well referenced up-to-date review of the subject one cannot help but agree with this sentiment, but as the nature and cause of aging raise basic fundamental questions in biology perhaps this is not too surprising.

The book is divided into four parts. The first is concerned with the possible molecular basis of aging which resolves essentially into error and programmed theories. The former assumes that aging results from the accumulation of errors in DNA replication or deficiencies in the repair of such errors. The latter assumes that aging results from genetically programmed senescence. Evidence is presented both for and against these two possibilities. The observation in man of increasing hypodiploidy in cultured lymphocytes with age, most frequently affecting the X chromosome in females and the Y chromosome in males, is intriguing, but whether this is a cause or effect of aging remains unresolved.

The second part of the book is concerned with aging at the level of the organism itself from protozoa and fungi to vertebrates. Whether certain findings in lower organisms are of general relevance is a mute point. For example, in *Podospora anserina* (a filamentous fungus) there is clear evidence that longevity is at least partly controlled by cytoplasmic factors. In higher forms life span and survivorship can be expressed in terms of allometric and Gompertz equations for which Sacher presents convincing explanations. It would seem reasonable, however, that aging in man is at least partly determined by genetic factors and the third and largest part of the book is devoted to this subject. In 1961 Hayflick first demonstrated that human diploid somatic cells have a limited replicative life span in tissue culture which is inversely related to the age of the donor. Since then, this has become an exciting and popular experimental tool for studying the phenomenon of aging at least as this is expressed *in vitro*. Detailed consideration is given to this phenomenon in the case of those genetic syndromes known

to be associated with premature aging such as progeria in which fibroblasts in culture show reduced survival, defective HLA expression, increased heat lability of cytoplasmic enzymes, changes in insulin receptors and tissue factors promoting clotting. These observations are appealing; but are such disorders a legitimate paradigm of normal aging? The possible role of genetic factors in aging is more directly approached by family and twin studies. The findings in the now famous Pearl (Baltimore) study of longevity among relatives of nonagenarians are discussed in detail and indicate that there is a definite familial component in aging. However, this is small and Murphy is careful to avoid being dogmatic as to its nature. It could well be largely cultural or environmental. On the other hand, the discussion of

twin studies gives more emphasis to a genetic component in aging.

The fourth and final part of the book is concerned with certain experimental approaches to aging, including somatic cell genetics, immunogenetics and behavioural genetics.

Inevitably in a work of this nature there is some repetition but this is less than in most large multi-authored books. In any event it is often interesting to compare the views of different contributors on the same subject; though the index itself is often unhelpful in this regard. This is a highly readable and well referenced review of a fascinating subject and I would recommend it without reservation.

Alan E. H. Emery

Alan E. H. Emery is Professor of Human Genetics at the University of Edinburgh, UK.

Nuclear transplantation experiments in Amphibia

Cloning: Nuclear Transplantation in Amphibia. By R. G. McKinnell. (University of Minnesota Press: Minneapolis, 1978.) \$22.50.

IN spite of its principal title, this book is not concerned with most aspects of cloning. Thus, it does not deal with cloning in plants, with the cloning of DNA or genes in bacteria by plasmids and phages, nor with the cloning of animal cells in culture. In fact the book consists entirely of an account of nuclear transplantation experiments in Amphibia, primarily those with *Rana pipiens*. This has its use, and a chapter on the transplantation of nuclei from tumour cells is clearly presented and well balanced.

Unfortunately the same cannot be said for much of the rest of the book. In general, work with species other than *R. pipiens* is treated as trivial or at best confirmatory. Often it is hard to discern the direction of an argument. Thus, the book does not make it clear that many amphibian nuclear transfer experiments have been addressed to the specific question of whether the nucleus of one kind of specialised cell contains the genetic information necessary to promote the formation of other quite unrelated cell types. Though generally considered important, this question is totally obscured in this book by the author's decision to emphasise the age rather than differentiated state of donor cells.

From the student's point of view, a

serious deficiency is that alternative but not exclusive interpretations are often omitted. For example, most of the first half of the book is concerned with abnormal embryos resulting from nuclear transfers in *R. pipiens*. It is therefore disappointing to find that one of the principal ideas regarding the significance of these abnormal embryos is entirely overlooked. The author presses the view that the abnormalities of nuclear transplant embryos may give specific information about the specialised state of gene control in donor cells. An alternative interpretation (favoured by several in this field) is that abnormal embryos result from random chromosomal losses due to the low replication rate of specialised cells and the very high rate at which eggs always divide. My criticism is not that the author subscribes to the former point of view, but to disguise or ignore the second interpretation seems to me to significantly misrepresent the literature.

The last half of the book contains useful technical information in the form of six appendices. These deal with the biology and maintenance of *R. pipiens*, the instruments, solutions and techniques used to transplant single nuclei to eggs (primarily *R. pipiens*), as well as with sources of various anuran species.

The unbalanced presentation and uncritical interpretation of nuclear transplantation experiments seriously limit the general usefulness of the first part of this book. However, the technical information in the appendices should prove valuable for those wishing to transplant nuclei in *R. pipiens*.

J. B. Gurdon is at the MRC Laboratory of Molecular Biology in Cambridge, UK.

NOW

A journal both for specialists interested in method development and researchers looking for new methods to solve biological, biochemical, biophysical and medical research problems.

JOURNAL OF BIOCHEMICAL AND BIOPHYSICAL METHODS

managing editor:

C.F. CHIGNELL

Laboratory of Environmental Biophysics
National Institute of Environmental
Health Sciences
P.O. Box 12233
Research Triangle Park
NC 27709, U.S.A.

associate managing editor:

S. HJERTÉN

Institute of Biochemistry
Biomedical Centre
University of Uppsala
Box 576
S-751 23 Uppsala
Sweden

AIMS AND SCOPE

Journal of Biochemical and Biophysical Methods will publish research papers dealing with the development of methods to solve biological problems. Articles may be concerned either with new methodology or with the significant modification of existing techniques. The scope of the journal is broad, encompassing all methodological aspects of biochemistry, biophysics and molecular biology. Although articles should be written in sufficient detail to allow easy verification they should also be intelligible to a broad scientific audience. In addition the journal will publish a section of short notes describing improvements in methods which, though significant, do not warrant a full-length research paper. Short review articles dealing with recent developments in a particular method or technique that are of interest to a broad scientific audience will also be published. Papers may be submitted to any member of the editorial board. Full instructions to authors may be obtained from the publisher or one of the managing editors.

System Design with Microprocessors

D. Zissos

with contributions by J. C. Bathory and a foreword by J. L. Alty

October/November 1978, approx. 230pp., £6.50/\$13.50 (paperback) 0.12.781750.6

Following his pioneering work in Logic Design, Professor Zissos now presents the field of microprocessors in an accessible and easy-to-read form. This book is designed to satisfy the current demand for knowledge about how microprocessors work and how they can be used. It is written in the direct, de-mystified style characteristic of Professor Zissos, and is designed not only for those with a specialist knowledge of electronics but also for non-specialists — such as system designers, communications experts, non-electronic engineers, physicists, chemists and medical experts who wish to construct their own microprocessor systems.

1st Volume in Biological Techniques —

A series of short texts for use at the laboratory bench

Ion-Sensitive Intracellular Microelectrodes

How to make and use them

R. C. Thomas

October/November 1978, approx. 410pp., £7.00/\$14.50 0.12.688750.0

This is essentially a laboratory handbook for experimenters. The author, himself a pioneer in the field, describes in detail the methods he and others employ to make and use ion-sensitive microelectrodes. Such microelectrodes permit the direct and continuous measurement of ion activities inside living cells. Since it has recently become possible to apply this technique to a wide variety of cells, this volume will be especially welcomed by research workers. The bulk of the book is practical in approach — though it begins with a brief historical introduction — and contains profuse and detailed illustrations. It concludes with an appendix listing sources of supply for the hard-to-obtain components.

Rhythmic Activity of Fishes

edited by J. E. Thorpe

October/November 1978, x + 312pp., £11.50/\$23.75 0.12.690650.5

It has been demonstrated repeatedly that living organisms respond in a rhythmic way to the regular oscillations of their environment. Information on rhythmicity of activity in fishes is accruing rapidly. This book — the proceedings of a symposium organised by the Fisheries Society of the British Isles — presents review papers contributed by sixteen experts. Four main topics were discussed at the meeting: the endocrine basis of rhythmic behaviour; physiological and behavioural rhythms; temporal aspects of community structure; and methods and instrumentation for use in the investigation of problems in these areas.

Developments in Clinical Immunology

Symposium sponsored by Bayrofarm Italiana S.P.A.

edited by M. Ricci, A. S. Fauci, P. Arcangeli and P. Torzuoli

October/November 1978, xvi + 266pp., £12.00/\$24.75 0.12.587180.5

This book presents the proceedings of the symposium "Developments in Clinical Immunology" organized by Professor Mario Ricci, Director of the Postgraduate School of Allergology and Clinical Immunology and held at the University of Florence. The aim of the conference was to bring together eminent scientists interested in both the theoretical and clinical aspects of immunology. Their papers provide a summary of the state of the art and of the recent advances that have been made in the field of atopy and lymphocytes. Undergraduates and graduate students will find it invaluable to have such a wealth of material gathered together under one cover sparing them from searching through diverse journals of allergy, immunology, biochemistry, physiology and pathology where such information is usually disseminated.

Rational Quadratic Forms

November/December 1978, xvi + 414pp., £17.50/\$36.25 0.12.163260.1

This monograph presents the main themes of the theory of quadratic forms at a level that can be appreciated by a wide variety of readers. The first half of the book develops the classical theory of rational and integral equivalence for quadratic forms with rational or rational integral coefficients. Full use is made of the insight and clarity provided by the use of p -adic numbers and of Witt's theory of quadratic spaces. The second half contains treatments of spinor genera, or reduction theory and automorphs, and of the composition of binary forms.

Orthopaedic Mechanics: Procedures and Devices

edited by Dhanjoo N. Ghista and Robert Roaf

October/November 1978, xli + approx. 350pp., £17.60/\$36.50 0.12.281650.1

This book aims to provide a state-of-the-art cum tutorial coverage of orthopaedic mechanics, procedures and devices. It provides quantitative information on the structure and mechanical properties of bone, and on the relationships between the kinetics and kinematics of the finger, knee and spine. It demonstrates how relevant mechanics analysis can be invoked in prescribing correction procedures and devices for deformities of the spine, knee and hand. Of clinical pertinence are sections dealing with the mechanical design considerations of systems providing lateral and distraction forces to the spine, arthroplasty devices and internal fixation devices (by means of screws, pins, wires, plates and intramedullary nails). The final chapter provides an implementable activities chart (accounting for fabricability, mechanical strength and biocompatibility testing complexities, costs and time scales) for design development of a new biomaterial-prosthetic device.

European Monographs in Social Psychology

Series editor: H. Tajfel

Number 14

Differentiation Between Social Groups**Studies in the Social Psychology of Intergroup Relations**

edited by H. Tajfel

October/November 1978, xvi + 474pp., £19.50/\$40.35 0.12.682550.5

Football fans, Maori children, factory shop stewards or engineering students — in spite of their apparent incongruities as common subjects for a single study — each possess a group identity and display complex intergroup relations, the description of which is one of the aims of this book, about the new theory and research related to it. How do social mobility, change or rigidity, conformity or deviance, self-identity versus group categorization, and majority or minority status affect inherent tendencies for people to differentiate themselves one from another? The basic thesis of this book is that there is a marked tendency to social differentiation rather than conformity, and that this tendency, as a national, ethnic, linguistic or individual level, both promotes social innovation and creativity and, equally, becomes a source of conflict and waste.

Metal β -Diketonates and Allied Derivatives

R. C. Mehrotra, R. Bohra and D. P. Gaur

October/November 1978, viii + 832pp., £20.50/\$42.40 0.12.488150.5

Presented here is a concise account of the developments made in different eras in the chemistry of metal β -diketonates. The book concentrates on four aspects: their synthesis, the nature of bonding and their aromatic character, their chemical reactions and their physical properties, including spectroscopic, magnetic and structural characteristics. There are now more than a hundred research papers published annually on different aspects of this fascinating field of chemistry. The present monograph covers around two thousand references to original literature and the authors have attempted to include all the major breakthroughs and developments of this fast growing subject.

Mammalian Metabolism of Plant Xenobiotics

R. R. Scheline

October/November 1978, xli + 502pp., £28.00/\$58.00 0.12.623350.0

Plant xenobiotics, which can roughly be equated with those compounds termed 'secondary plant metabolites', are of considerable importance in many fields of research such as pharmacology, toxicology, medical and natural products chemistry, and food sciences. It is important therefore that information on their metabolites and the pathways leading to them, is readily available to those working in such active areas of research. A large quantity of literature on xenobio-chemistry has been published in recent years, but references are scattered and location of an overall summary of the metabolism of a specific compound is often difficult and time consuming. Accordingly, this volume has been compiled to provide a comprehensive survey of the current knowledge in a specific part of this large field, namely that of plant xenobiotics.

APPOINTMENTS VACANT

THE UNIVERSITY OF LEEDS DEPARTMENT OF PLANT SCIENCES

Applications are invited for the temporary fixed-term post of post-doctoral RESEARCH FELLOW to work with Dr L. D. Incoll on a project concerned with work on when and how cytokinins open graminaceous stomata.

Ideally applicants should have been trained at the postgraduate level in research on phytohormones and should have research experience in that field. Appointment is for one year in the first instance, renewable for up to a total of three years. Initial salary will be in the range £3,883 to £4,382 per annum (within the 1A range of the scale for Research and Analogous staff). (Under review.).

Applications, giving curriculum vitae and the names of two referees, should be sent by October 5, 1978 to Dr L. D. Incoll, Department of Plant Sciences (Baines Wing), The University of Leeds, Leeds LS2 9JT, from whom further details may be obtained. Closing date for applications has been revised to October 20, 1978, in view of the fact that this advertisement did not appear in the journal at the appropriate time. 7073(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF METALLURGY

Applications are invited for the post of POSTDOCTORAL RESEARCH FELLOW in Photo-Emission Electron Microscopy to participate in a wide range of physical metallurgical work in the Department, with special emphasis on high temperature and deformation phenomena. The successful applicant will be responsible for the organisation of work carried out on the Photo-Emission Electron Microscope together with the training of associated technical staff and research students who will operate it. Candidates should have a Ph.D. in a relevant scientific or engineering field or be in the process of completing their thesis. Previous research experience involving electron microscopy and/or the use of vacuum equipment would be an advantage.

Initial appointment will be made at an appropriate point in the range £3,883 to £4,631 (under review) on the 1A Scale for Research and Analogous Staff.

Applications, with the names of two referees, should be sent to Professor J. Nutting, Department of Metallurgy, The University of Leeds, Leeds LS2 9JT by October 16, 1978. 7307(A)

HERIOT-WATT UNIVERSITY RICCARTON

MARINE SCIENCE UNIT
INSTITUTE OF OFFSHORE ENGINEERING
RESEARCH ASSOCIATES (THREE POSTS)
Salary scale £3,384 to £4,882 (under review)

RESEARCH TECHNICIAN
Salary in range £2,688 to £3,720 (under review)

Applications are invited for the above posts. The successful applicants would join a team investigating the nature, fate and effects of hydrocarbons and other pollutants in industrial effluents, shellfish and marine sediments, under programmes supported by industrial contract and research grants.

Applicants for the Research Associate posts should have an honours degree in chemistry or biochemistry, preferably with experience in chromatographic (notably gc) techniques. Driving licence and/or ability to dive (SCUBA) desirable but not essential.

Applicants for the post of Research Technician should have appropriate educational qualifications in chemistry and experience in handling and maintenance of high resolution chromatographic equipment.

Informal enquiries may be made to Dr C. S. Johnston, Director of the Marine Science Unit, telephone 031 449-5111, Ext. 2382.

Application forms are available from the Staff Office, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX, to whom the completed forms should be returned as soon as possible. 7323(A)

Microbiologist £2,839 - £6,898

Applications are invited for a pensionable post in the Department of Agriculture's Agricultural and Food Bacteriology Division, Newforge Lane, Belfast.

The successful candidate will be expected to undertake research and investigational work connected with the microbiology of foods and may also be required to undertake lecturing duties in the Faculty of Agriculture and Food Science, Queen's University, Belfast.

Appointment may be at Senior Scientific Officer, Higher Scientific Officer, Scientific Officer level.

SENIOR SCIENTIFIC OFFICER

Over 25 and under 32 years of age on 31 December 1978 with a 1st or 2nd class Honours Degree in Microbiology, and at least 4 years appropriate postgraduate experience.

HIGHER SCIENTIFIC OFFICER

Under 30 years of age on 31 December 1978 with an Honours Degree as above and at least 2 years appropriate postgraduate experience.

SCIENTIFIC OFFICER

Under 27 years of age on 31 December 1978 with an Honours Degree as above.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available (including level of academic attainment) to be best qualified.

SALARY SCALES

Senior Scientific Officer — £5,154-£6,898

Higher Scientific Officer — £4,101-£5,448

Scientific Officer — £2,839-£4,415

Grading and starting salary will be related to qualifications and experience.

Please write or telephone for an application form quoting job reference SB 359/78/N to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 Ext 257). Completed forms must be returned to arrive not later than 19th October 1978. 7345(A)

M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital)

Watford Road, Harrow, Middx. HA1 3UJ

Technician required to operate and maintain a gas chromatography-mass spectrometry-computer facility in the Division of Clinical Chemistry.

Applicants should have a primary interest in instrumentation and electronics and preferably have a general background in analytical chemistry. Previous mass spectrometry experience would be an advantage but is not essential. Minimum academic standard required would be an HNC in physics, chemistry or related subject.

Salary within the range £3,615 to £5,034 incl. L.W. Application forms and job description from Mrs J. Tucker-Bull quoting reference 106/2/4004. Closing date October 20th.

7338(A)

THE UNIVERSITY OF BRITISH COLUMBIA

Department of Chemistry

POSTDOCTORAL RESEARCH POSITIONS

Applications are invited from well qualified candidates for one or two year appointments as Postdoctoral Research Fellows in the following fields:—

Atmospheric photochemistry; Bioinorganic chemistry; Catalysis studies, diffusion and phase separation on surfaces; Catalysis using transition metal complexes; Chemical Oceanography; Development of New Synthetic Methods in Organic Chemistry; Electron impact and Photoelectron Spectroscopy including Auger and ESCA studies; Electron paramagnetic, ENDOR, NQR, Mossbauer, microwave, electronic and LEED spectroscopies; Flash photolysis and Kinetic Spectroscopy; Fluorocarbon Chemistry; Homogeneous Catalysis; Immunochemistry of polysaccharides; Inorganic photochemistry and photo-physics; Kinetic theory of gases applied to aeronomy and space science; Lipid synthesis for NMR study of biomembranes; Mechanism of Intercalation of layered Structures; Muonium Chemistry at TRIUMF; NMR and laser Raman spectroscopy of nuclear spin labelled nucleic acids; Non-linear optical effects in organic solids at low temperature; Nuclear magnetic resonance studies of molecular motion; Organic Solid State Reactions; Organometallic Chemistry; Oxidation, use of coenzyme models, general acid catalysis; Potential antiviral and antitumor compound synthesis; Quantum chemistry and Molecular Physics; Radiation chemistry and solvated electron studies; Synthesis and study of organic metals; Theory of molecular relaxation and transport properties; X-ray diffraction studies.

The minimum stipend for the first year will be \$11,100. A substantial number of Teaching Postdoctoral Fellowships, with a minimum stipend of \$13,750, are also available. Killam Postdoctoral Fellowships, with stipends of \$14,000, are open to students who have recently graduated and have shown superior ability on research and scholarship.

Send curriculum vitae, transcripts, and letters from three referees to the undersigned, from whom further particulars may be obtained.

AGRICULTURAL RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY BABRAHAM, CAMBRIDGE CB2 4AT

RESEARCH SCIENTIST

required in the Physiology Department to carry out research into biologically-active peptides and proteins (e.g. gastro-intestinal hormones, somatomedins, hypothalamic peptides), their isolation, characterisation and mechanism of action. Salary in H.S.O. (£4,101 to £5,448 per annum) or S.S.O. (£5,154 to £6,898 per annum) scale according to experience. Candidates should have first or upper second class honours degree in physiology or biochemistry, with at least two years' relevant postqualifying experience. Preference for Ph.D. Non-contributory superannuation scheme. Applications to the Secretary of the Institute by October 30, 1978. Quote Ref. A.M.B.3. 7299(A)

THE POLYTECHNIC OF CENTRAL LONDON Bio-organic Research Group RESEARCH ASSISTANT IN MICROBIAL ENZYMOLOGY £3,015 to £3,189

To work on the cellulose-degrading enzymes produced by bacteria. The successful candidate will join a small team of biotechnologists working on the production and properties of cellulases.

Applicants should have a good class degree in an appropriate subject and will be able to register for a higher degree.

Further details and application form, which should be returned as soon as possible, from the Establishment Officer, P.C.L., 309 Regent Street, London W1R 8AL (tel. 01-580 2020, ext. 212). 7300(A)

INSTITUTE OF DERMATOLOGY (University of London)

require a

TECHNICIAN

to work in the laboratories of the Professorial Unit. The successful candidate will work on the development and use of radioimmunoassays for pharmacological mediators related to inflammation in human skin. Preference will be given to applicants with experience in radioimmunoassay techniques.

Applications, giving details of age, qualifications, experience and the names of two referees should be sent to Dr N. A. Plummer, Institute of Dermatology, Homerton Grove, London E9 6BX. 7302(A)

ROYAL MARSDEN HOSPITAL FULHAM ROAD, LONDON SW3. Medical Laboratory Scientific Officer—Immunology £3,615 to £5,034

Applications are invited from medical laboratory scientific officers experienced in tissue typing, for a post which is available immediately. The duties include screening and identifying HLA antibodies, typing of patients and potential donors for the bone marrow transplantation programme, and participation in regional and international workshop exchanges of antisera and information. New developments include the identification of B-cell antibodies and the application of these to studies in malignant disease.

Application forms from Personnel Dept. Tel. 352 8171, ext. 447. Closing date: October 16, 1978. 7295(A)

THE CHINESE UNIVERSITY OF HONG KONG FACULTY OF MEDICINE

Applications are invited for the following foundation chairs:

ANATOMY PHYSIOLOGY PHARMACOLOGY

tenable at this new medical school with an annual student intake of 100. There will be opportunities for original research but considerable undergraduate teaching experience is essential. Non-medically qualified candidates may apply but preference will be given to those medically qualified. Successful applicants are expected to be in post latest end of 1980 or early 1981, to take part in compiling the basic medical sciences curriculum and installing departmental facilities. Teaching will begin in the fall term of 1981. The minimum salary for Professorships will be HK\$11,735 per month (£1=HK\$9.2). Terms of service also include long leave, superannuation benefits (University 15%, appointee 5%), housing accommodation on campus and air passages. Full particulars of the appointment, together with copies of relevant documents concerning the medical school and the University may be obtained from the Secretariat, The Chinese University of Hong Kong Shatin, New Territories, Hong Kong, to which applications (6 copies) giving full details of qualifications and experience and the names and addresses of 3 persons to whom reference may be made should be sent not later than December 15, 1978. 7251(A)

Job Announcement

ARMAUER HANSEN RESEARCH INSTITUTE (A.H.R.I.) INSTITUTE DIRECTOR (LEPROSY RESEARCH)

The position of Institute Director will be available June 1, 1979 or earlier at the Armauer Hansen Research Institute (AHRI), Addis Ababa, Ethiopia. AHRI undertakes basic research on the etiology, pathogenesis and immunology of leprosy. The Institute was founded in 1969 and is operated by the Save the Children organisations of Norway and Sweden.

The Institute is well-equipped for research within the areas of microbiology and immunology, and is located at the All Africa Leprosy Rehabilitation and Training Centre (ALERT) which makes it possible to do clinically oriented studies on patients in ALERT's hospital. The Institute staff consists at present of three senior researchers, a research assistant, two research fellows, a laboratory engineer, a lab technician, four lab assistants, a chief administrator, two secretaries and other personnel—altogether 24 persons.

The Institute Director is responsible for the operation of the Institute as well as leading the research work. Applicants should have well-documented background in microbiological and/or immunological research, preferably a medical degree, although this is not an absolute requirement. Applicants normally must agree to a contract of at least two years.

Further information concerning this position can be obtained from Professor Morten Harboe, Institute for Experimental Research, Ullevål Hospital, Oslo 1, Norway. Telephone 472/60 03 90.

Applications accompanied by a curriculum vitae, a list of publications and personal references should be sent before November 1, or within three weeks after the appearance of this announcement to REDD BARNA (Norwegian Save the Children), Lillestorg 1, Oslo 1, Norway. 7301(A)

Promote Polaroid Medical Diagnostics Material and let Polaroid promote your career

Home Counties c. £5,700 plus car

Put your technical or sales knowledge to good use with our client, Polaroid, whose films and equipment are among the leaders in the field of medical diagnostics. Their systems are used in the areas of computed tomography, ultrasound, nuclear medicine and thermography and there is a corporate commitment to the development of products and sales in this important market.

You will be in your 20s or early 30s, educated to at least 'A' level standard and with an appropriate technical background gained from radiography, nursing or as a representative for medical equipment and disposables. You will be expected to become an expert and advisor in the medical applications of the Company's products.

You will also need the will to sell and the ability to pass on your product knowledge to Polaroid's regular sales personnel.

Your work will also involve you in the sales of the whole range of Polaroid's technical films and systems in a home counties based sales area. The experience you will gain will provide you with the key to the promotion in sales and marketing in this go ahead Company.

The opportunities for any woman or man are limited only by their ability and drive - Polaroid have a vested interest in your success! On offer are first rate salary and car (Cortina 1600GL Estate), progressive benefits, knowledge and relocation assistance if appropriate.

Find out more from David Woolf on Hertford (0992) 50541, or write to him for an application form to The Personnel People, 95 Fore Street, Hertford SG15 1AS.

UNIVERSITY OF GEORGIA ATHENS, GEORGIA

Applications are invited for the post of

POSTDOCTORAL RESEARCH ASSISTANT

Tenable from October 15, 1978 for one year, for the study of the breakdown metabolites of a plant growth regulator. Applicants should preferably have experience in plant biochemistry and radioisotope technique.

Salary in the range of £6,000 to £6,500 per annum plus University of Georgia faculty benefits.

Applications, including a curriculum vitae and the names of two referees should be addressed to Dr S. J. Kays, Department of Horticulture, Plant Science Building, University of Georgia, Athens, Georgia 30602.

7340(A)

UNIVERSITY OF SOUTHAMPTON FACULTY OF MATHEMATICAL STUDIES CHAIR OF OPERATIONAL RESEARCH

Applications are invited for the Chair of Operational Research. Salary within the professional range. Applicants should have an established reputation in the field of Operational Research. Further particulars may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH, and applications (11 copies from applicants in the United Kingdom) must be submitted before November 28, 1978. Please quote ref MA2/1/Na.

7331(A)

CENTRO DE INVESTIGACIONES Y DE ESTUDIOS AVANZADOS Mexico City, Mexico

Two positions exist in the Department of Genetics and Molecular Biology for Assistant/Associate Professors working with pro- or eukaryotic microorganisms. Laboratory facilities are excellent; teaching responsibilities minimal; knowledge of Spanish is not necessary. Applicants should possess a Ph.D. Send curriculum vitae, names of three references, synopsis of research and reprints to: Dr Jose Ruiz Herrera, Depto de Genética y Biología Molecular, C.I.E.A. del I.P.N., Apartado Postal 14-740, Mexico 14, D.F.

7281(A)

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts, AL5 2JQ ORGANIC CHEMIST

Applications are invited from synthetic organic chemists for a three-year position. The appointee will be expected to synthesise analogues of amino acids and will be involved in their use both at Rothamsted and at the commercial concern sponsoring the project.

Qualifications: 1st or upper 2nd class honours degree in a relevant discipline with at least three years' research experience in organic synthesis. Preference will be given to candidates with a Ph.D. in a relevant subject.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,448) Non-contributory superannuation.

Applications, giving names and addresses of two referees and quoting reference 352 to the Secretary by October 19. Further details on request.

7370(A)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY, BABRAHAM, CAMBRIDGE CB2 4AT BIOCHEMIST

required to join group studying the structure and distribution of antigen determinants in cell membranes and their role in transport processes. Applicants should have an interest in immunology and preferably experience in the preparation and use of conjugated antisera, and/or analysis of glycoproteins. Preference will be given to candidates possessing, or expecting to possess, a Ph.D. or equivalent. The appointment, which is financed by a grant from the M.R.C. is for three years commencing as soon as possible. Salary in scale £4,101 to £5,448 per annum according to qualifications and experience. Applications together with the names of two referees to the Secretary of the Institute from whom further information may be obtained. Ref E.M.T.6

7292(A)

KINGSTON POLYTECHNIC SCHOOL OF GEOLOGY RESEARCH ASSISTANT

to work on the sedimentology and related volcanicity of the middle caradocian rocks in Snowdonia, North Wales. Applicants should have a good honours degree in Geology, including the techniques used in sedimentology and structural geology, and should preferably have some knowledge of volcanic rocks.

The research will be conducted under the supervision of J. N. Diggins and Dr P. J. C. Sutcliffe.

The successful candidate will be expected to register for a higher degree. Salary range £2,910 to £3,084 per annum.

Further details and application forms from Academic Registry, Dept AO, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE 01-549 1366.

7341(A)

QUEEN CHARLOTTE'S MATERNITY HOSPITAL Goldhawk Road, London, W6 BASIC GRADE OR SCIENTIFIC OFFICER (Cytogenetics)

Applications are invited from Science Graduates with honours degrees for the above posts. Preference will be given to candidates with experience of diagnostic work in human cytogenetics. Whitley Council terms and conditions of service. The diagnostic laboratory, which is fully equipped, may be visited by appointment. Intending applicants are advised to contact Dr D. Hughes (Tel: 01-748 4666, Ext: 223) in the first instance.

Application forms obtainable from and returnable to the Administrative Assistant (Ext. 204).

7329(A)

MEDICAL LABORATORY SCIENTIFIC OFFICER (OR JUNIOR)

required for varied endocrine analytical work in DEPARTMENT OF GYNEACOLOGY (Biochemistry Laboratory) H.N.C. standard needed or 'A' level chemistry for junior post. Apply giving age and details of qualifications and experience to Dr M. G. Brush, St Thomas' Hospital Medical School, London SE1 7EH.

7282(A)

Medical Research Council Cell Biophysics Unit

Appointment of Director

The present Director of the MRC Cell Biophysics Unit, Professor M. H. F. Wilkins, CBE, has indicated his wish to resign in the near future. The Council now wish to proceed to the appointment of a Director to succeed him.

The Unit is accommodated in the Department of Biophysics, King's College, London, with which it has a close relationship and shares a number of common facilities. The work of the Unit is to be centred on the biophysical, biochemical and structural study of the mechanisms involved in the control of cell shape and motility (currently with particular reference to the nervous system and to skeletal muscle) but this need not exclude any other aspects of research in cellular biophysics to take into account the Director's own interests. The person appointed as Director, who will be a full-time member of the Council's staff, must have an established reputation as a scientific investigator in a relevant field and the ability to play a leading role in initiating and managing research using a variety of disciplines and techniques. An appointment to the Council's staff will be in accordance with the Council's terms and conditions of service, with superannuation provision under the MRC pension scheme. The salary will be within the range for the Council's Special Appointments grade, which is equivalent to the university professorial range although, exceptionally, a higher salary might be agreed.

Applications for the post are now invited from men and women, and should comprise a *curriculum vitae*, a list of publications, the names of 3 persons to whom reference might be made, and a short statement (not exceeding 500 words) outlining in general terms the scientific programme that the applicant would wish to undertake and indicating how it would relate to the central theme of the Unit's work. These details (12 copies) should be submitted not later than November 10, 1978 to the Secretary, Medical Research Council, 20 Park Crescent, London W1N 4AL. Further information about the appointment and the Unit, including details of its present programme, may be obtained from Dr M. B. Kemp, at the same address (tel: 01-636 5422). The Council reserves the right to invite applications from persons other than those who respond to this advertisement. 7380(A)

MRC
Medical Research Council

THE UNIVERSITY OF BRITISH COLUMBIA DEPARTMENT OF ZOOLOGY

Applications are invited for the position of Assistant Professor in the Department of Zoology, University of British Columbia. Qualifications include a Ph.D. in biology or a related field, with a demonstrated ability to teach introductory biometrics. The successful applicant will be expected to develop a strong experimental research programme. Upper level undergraduate teaching, and graduate student teaching and supervision is required. Salary will be commensurate with experience and duties. Curriculum vitae and the names of three referees should be submitted to Dr G. G. E. Scudder, Head, Department of Zoology, University of British Columbia, 2075 Westbrook Mall, Vancouver, B.C. V6T 1W5, Canada. The expected date of appointment is July 1, 1979, subject to budgetary approval. Closing date for application is when position is filled. 7305(A)

UNIVERSITY OF WARWICK RESEARCH TECHNICIAN

The Department of Biological Sciences has vacancies in the Microbiology Research Group for technicians to work on the isolation and purification of enzymes from methane oxidising bacteria.

Applications are invited from graduates and others with appropriate qualifications and experience in biochemistry and/or microbiology. One of the posts is for a contract period of 2 years.

Salary will be either on the Technician Grade 2 scale: £2,688 to £3,060 p.a. (both under review).

Application should be made by letter giving full details of age, qualifications, experience, etc., to the Personnel Office, University of Warwick, Coventry CV4 7AL by October 13, 1978. Please quote Ref. No: 9/2D/78. 7373(A)

UNIVERSITY OF GLASGOW POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a University Research Assistantship to be filled at postdoctoral level. The post is with a group studying the molecular biology of antibody formation with emphasis on the application of recombinant DNA technology. Experience in molecular immunology or recombinant DNA techniques is desirable.

The position is available from October 1, 1978.

Salary will be within Range 1A of the salary scales for Research and Analogous Staff (£3,883 to £6,555, under review) with appointment at a point appropriate to age and experience.

Application with curriculum vitae and names of two referees should be sent as soon as possible to Professor A. R. Williamson, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No. 4248M. 7342(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF HISTOLOGY AND CELL BIOLOGY (MEDICAL) SENIOR RESEARCH ASSISTANT

Applications are invited for the above post to join a group studying the interrelationships between the cell surface, the cytoskeleton and the extracellular matrix. Experience or an interest in electron microscopy will be an advantage. The appointment will start as soon as possible and in the first instance will be for one year only.

Initial salary £3,883 or £4,133 per annum.

Applications, together with the names of two referees, should be received not later than October 20, 1978, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/947/N. 7347(A)

NEWCASTLE UNIVERSITY HOSPITALS ROYAL VICTORIA INFIRMARY NEWCASTLE UPON TYNE POSTDOCTORATE SCIENTIFIC OFFICER

required for three year project concerned with clinical and experimental study of cellular immunology in lymphoproliferative disease. The post is available immediately and will be run in Department of Haematology, in the main Newcastle teaching hospital.

Previous laboratory experience in cellular immunology tissue culture or serology is essential.

Starting salary £4,130.
Contact Dr S. J. Proctor, Department of Haematology, Royal Victoria Infirmary, Newcastle upon Tyne (telephone 25131, extension 7). 7348(A)

KINGSTON POLYTECHNIC SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES RESEARCH ASSISTANT

Applications are invited from candidates with a good honours degree in or including Physics, to study the ultrasonic production of cavitation and its effects on living cells. The successful applicant will be expected to register for a higher degree.

Salary range £2,910 to £3,084 inclusive.

Application forms and further details from Academic Registry, Dept. AO, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366. 7367(A)

Re-advertisement SHEFFIELD CITY POLYTECHNIC DEPARTMENT OF BIOLOGICAL SCIENCES RESEARCH ASSOCIATE IN BIOLOGICAL SCIENCES

Salary Scale: £4,101 to £6,558

This is one of two posts of Research Associate created in the Polytechnic to provide leadership and direction of research in specific areas. The research activities of the Department are concentrated mainly in the areas of Microbial Biochemistry, Animal Physiology and Biochemistry.

Applicants must be well qualified and experienced in one of the above areas and have previous experience of research supervision. Recent industrial experience would be advantageous.

The appointment is for a fixed period of three years.

Requests for an application form in writing only please to the Recruitment Section of the Personnel Department, Sheffield City Polytechnic, (Dept. NA), Halfords House, Fitzalan Square, Sheffield S1 2BB. Completed forms should be returned by October 20, 1978. 7324(A)

UNIVERSITY OF SOUTHAMPTON LABORATORY TECHNICIAN (Physiology)

Applications are invited for an appointment as a Laboratory Technician (Physiology) in the Neurophysiology Group of the School of Biochemical and Physiological Sciences. The successful applicant will be required to assist in the running of Physiology undergraduate and postgraduate (M.Sc.) practical classes and with maintenance and operation of the relevant laboratories. Duties will include some technical support for research in Neurophysiology and allied disciplines.

Minimum qualifications: O.N.C./O.N.D. or equivalent with three years relevant experience. The appointment will be made at grade three on salary scale £2,688 to £3,060 per annum (under review).

Applications giving date of birth, qualifications and experience and the names and addresses of two referees, should be sent to Mr C. N. Saul, The University, Southampton SO9 5NH quoting reference number 482/T./Na. 7337(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY RESEARCH ASSOCIATE

Applications are invited for a post of Research Associate (preferably postdoctoral) to join an M.R.C. Programme Grant Project team investigating urinary enzyme excretion in normal and complicated pregnancies. Candidates should have a higher qualification and previous experience in enzyme biochemistry, preferably in relation to renal metabolism. The post is available for up to five years. Commencing salary within the range £4,130 to £5,506 per annum on the National Range 1A scale. Membership of the appropriate University Superannuation Scheme will be required.

Applications giving full curriculum vitae and the names and addresses of two referees should be submitted to Dr J. M. Davison, Princess Mary Maternity Hospital, Newcastle upon Tyne NE2 3BD within three weeks of the appearance of this advertisement. 7321(A)

Nature Conservancy Council

**SCIENTIFIC/HIGHER
SCIENTIFIC OFFICER****SALARY SCALE**

Scientific Officer - - - £2,839 - £4,415

Higher Scientific Officer - £4,101 - £5,448

Applications are invited for the post of Scientific Officer/Higher Scientific Officer in the Nature Conservancy Council Geological Conservation Review Unit Based at Newbury, Berkshire.

The geological work of the Nature Conservancy Council includes the identification and conservation of those localities that are essential to the continued study of geology and physiography; the provision of advice and dissemination of knowledge, both within and outside the NCC; and liaison with interested bodies and individuals. The duties do not include geological and geomorphological research.

THE POST

The Unit is responsible for the preparation of the Geological Conservation Review. The successful candidate will act as Assistant Head of the Unit, taking special responsibility for the localities of Quaternary interest. He/she will be liable, however to secondment to the G & P Section specifically dealing with case work, advisory duties and liaison related to the conservation of localities of Quaternary interest.

AGE AND QUALIFICATIONS

All candidates should have a first or good second class honours degree, or equivalent in Geology and/or Physical Geography with special emphasis and interest in Quaternary studies. A knowledge of photography is desirable.

SCIENTIFIC OFFICERS: Candidates should be under 27 years of age.

HIGHER SCIENTIFIC OFFICERS: Candidates should be under 30 years of age and have at least two years relevant post-graduate experience.

A current driving licence is essential.

Application forms and further details are available from Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs, PE18 6BU (Tel: 0480 56191).

Closing date for completed application forms is 3 November 1978.

SCIENTIFIC EDITOR

PHARMACEUTICAL RESEARCH AND
NEW PHARMACEUTICAL PRODUCTS

We publish Scrip World Pharmaceutical News, the leading international pharmaceutical industry weekly business magazine. Following the promotion of the present editor to a new post, we wish to appoint a scientific editor who will be responsible for reporting on international pharmaceutical research and new drug development and marketing.

QUALIFICATIONS: A good degree in pharmacy, pharmacology or biochemistry; A knowledge of one or more European language(s) would be an advantage; and experience of technical medical writing.

THE WORK: To write comprehensively about all aspects of research and marketing of new medical products around the world using a wide range of information sources including attending international conferences.

EXPERIENCE: We are looking for someone who is able to analyse and review medical data and has experience of technical writing. He or she may have worked either for a technical medical publication, in a pharmaceutical company's technical information department, or in a university or government department.

THE SALARY: Dependent on experience and qualifications: We will pay the right person a competitive salary to what he/she is currently earning.

If you would like to be considered for this key position in our team of writers please write, in confidence, giving details of yourself and your career to date to:

Dr P. J. BROWN
P. J. B. PUBLICATIONS LTD.
53a GEORGE STREET,
RICHMOND
SURREY TW9 1HE.

PJB

NEWCASTLE UPON TYNE POLYTECHNIC DEPARTMENT OF MATHEMATICS, STATISTICS AND COMPUTING RESEARCH ASSISTANT

To investigate 'Mathematical Modelling of Nozzle Blockage'. The successful candidate will join a research group which is active in the field of mathematical modelling and will undertake a research project concerned with the mathematical modelling of the formation of crusts on the inside of nozzles through which molten metals are being poured. Particular emphasis will be given to the problem of nozzle blockage. The project is being carried out in collaboration with the British Steel Corporation. The Research Assistant will be encouraged to register for a higher degree.

This appointment offers a salary of £3,162 to £3,555 per annum and is initially for two years.

For further particulars and application forms, returnable by Thursday, October 19, 1978, please send a stamped addressed foolscap envelope to the Staffing Officer, Newcastle upon Tyne Polytechnic, Ellison Building, Ellison Place, Newcastle upon Tyne NE1 8ST. 7325(A)

DALHOUSIE UNIVERSITY Halifax, Nova Scotia DEPARTMENT OF ANATOMY Position Open: PROFESSOR OR ASSOCIATE PROFESSOR

Applications are invited from persons with an M.D. or Ph.D. degree for the above position which will be available July 1, 1979. Experience in teaching medical Gross Anatomy and an established research program are required. Duties may also include the teaching of Anatomy to Medical, Dental, Health Professional and/or Science students and an ability to teach Neuroanatomy or Histology would be an advantage. Salary and rank commensurate with qualifications and experience. Applications, together with curriculum vitae and the names of two referees should be addressed to Dr D. G. Gwyn, Head, Department of Anatomy, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7. 7322(A)

THE UNIVERSITY OF BIRMINGHAM DEPARTMENT OF CLINICAL GENETICS LECTURESHIP IN HUMAN GENETICS

Applications are invited for the post of Lecturer (Non-clinical scale) in the Department of Clinical Genetics.

The successful candidate will work in the Infant Development Unit of the Birmingham Maternity Hospital in the Queen Elizabeth Medical Centre, adjacent to the University campus. The Unit has teaching, research and N.H.S. service commitments primarily in the fields of clinical genetics, population genetics, chromosomal mapping, complement typing, the interpretation of pedigree data by numerical methods, and the computational problems associated with transplantation. The Unit is associated in its work with the tissue typing and regional cytogenetics laboratories, and with the Universities of Iceland and Newfoundland.

Applicants should have a postgraduate degree or, if medically qualified, membership of a Royal College. Salary Scale: Non-clinical; £3,883 to £7,754 per annum plus superannuation.

Applications naming three referees should be sent to the Assistant Registrar, the Medical School, Birmingham B15 2TJ not later than November 18, 1978, quoting reference number LEC/CG/178. Further details may be obtained from Professor J. H. Edwards, Infant Development Unit, Birmingham Maternity Hospital, Birmingham B15 2TG. 7317(A)

UNIVERSITY OF READING POSTDOCTORAL RESEARCH ASSISTANT GEOCHEMIST

required as soon as possible, for a fixed term to be determined, for research on volatiles in magmas and minerals. The project funded for three years by the N.E.R.C. is supervised by Professor D. K. Bailey and is to apply new techniques to the extraction and analysis of gases from glassy lavas, and volatile-bearing minerals, with the aim of elucidating igneous and ore-forming processes. Applicants should already have a doctorate (or be submitting a thesis) in geochemistry. Experience in experimental petrology, mass spectrometry, or gas chromatography will be an advantage. Salary £3,883 per annum plus U.S.S. superannuation. Apply quoting Ref. M.N. 48A by November 6, with curriculum vitae and the names of two referees to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. 7360(A)

UNIVERSITY OF STRATHCLYDE PROFESSOR OF FORENSIC SCIENCE

Applications are invited from suitably qualified and experienced candidates for appointment to the newly established Professorship in Forensic Science.

Applicants should have substantial experience in one or more of the major aspects of Forensic Science, and be capable of directing postgraduate teaching and research as well as contributing to casework studies.

The post will be remunerated within the professorial range for universities with superannuation benefit.

Application forms and further particulars (quoting 48/78) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by November 8, 1978. 7359(A)

BRITISH POSTGRADUATE MEDICAL FEDERATION (University of London)

Geoffrey E. Duveen Fund
FOR THE PROMOTION OF
RESEARCH IN OTOTOLOGY

Applications are invited for support from the Geoffrey E. Duveen Fund for research in aspects of Otology and Neuro-Otology. Funds, which will be available during 1979/80, may be used either for:-

(a) A Junior Fellowship, to be called the 'Geoffrey E. Duveen Fellowship', normally tenable in a School of the University or an Institute of the British Postgraduate Medical Federation for a period of one year, with a possible extension for a second year. The stipend will be within the annual range of £3,600 to £4,600.

(b) To provide financial assistance in the form of grants towards technical assistance or the expenses of appropriate research conducted in Schools of the University or Institutes of the Federation.

Applications should be sent to the Director, British Postgraduate Medical Federation, 33 Millman Street, London WC1N 3EJ, by October 31, 1978. Applicants under (a) should submit a full curriculum vitae, details of the research proposed and the names and addresses of two referees. Applicants under (b) should submit particulars of the project for which they require financial assistance and details of the cost of technical assistance or equipment required. 7354(A)

TECHNICAL UNIVERSITY
OF CRETE
ADMINISTRATIVE
COMMITTEE
ANNOUNCEMENT

The Administrative Committee of the Technical University of Crete is interested in compiling information concerning scientists who may be interested in taking a professional or research position in one of the Schools or Research Institutes of the University. It therefore invites all who may be interested in such a position, to send to the Main Office of the university (Zaimi 2, Athens TT 148, GREECE, Attention: Professor P. Theoharis) a Curriculum Vitae containing full name and address, scientific accomplishments and areas of scientific interests. In this way the Administrative Committee will be able to keep informed about the vacancies, those interested in them.

It is expected that at the beginning of the next calendar year there will be 15 new professional positions in the first three Schools and two Research Institutes, of the University. The creation of more positions for the remaining Schools and Institutes will take place gradually within a couple of years.

For more detailed information please send your inquiries to the address given above. 7362(A)

ROTHAMSTED
EXPERIMENTAL STATION
Harpenden, Herts. AL5 2JQ
ENTOMOLOGIST

required to act as co-ordinator of a team in the Entomology Department working on the integrated control of cereal pests. The appointee would also be expected to study individually the biology, behaviour and ecology of a group of natural aphid predators/parasites relevant to the integrated control studies.

Qualifications: First or upper second class honours degree in applied entomology or zoology, with at least two years' postgraduate research experience. An interest in crop husbandry and possibly taxonomy would be an asset.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum), depending on experience. At least four years' relevant postgraduate experience required for Senior Scientific Officer. Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref. 371 by October 27, 1978. Further details on request 7326(A)

THE UNIVERSITY
OF HULL
DEPARTMENT OF
ZOOLOGY
CHAIR OF
APPLIED ZOOLOGY

Applications are invited for the Chair in Applied Zoology tenable from January 1 or at a later date to be arranged. The Professor will take the lead in diversifying the teaching base within the Department. Applications are invited from persons who consider their scientific experience would provide the impetus for new developments into the field of Applied Zoology, which the University views in its broadest interpretation as the application of animal biology to human affairs.

Initial salary will be not less than £9,443 per annum plus F.S.S.U./U.S.S. benefits.

Applications (12 copies) naming three referees should be sent by November 6, 1978 to the Registrar, The University of Hull, Hull HU6 7RX from whom further particulars may be obtained. 7320(A)

CSIRO AUSTRALIA Plant Breeder Research Scientist or Postdoctoral Research Fellow Division of Horticultural Research

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,200 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Salinity Research

Location:

The Division has laboratories at Adelaide, South Australia (Headquarters) and Merbein, Victoria. The successful appointee will be located at the Merbein laboratory.

General:

The Division is concerned with research on a range of perennial horticultural plants (deciduous and evergreen) from both temperate and subtropical regions. Current programs include studies on the management and genetic improvement of grapevines and fruit trees and of plant viruses and plant parasitic nematodes. Research in plant physiology, biochemistry and cytology relates to photosynthesis, salinity and plant and fruit development.

Duties:

To develop and select salt tolerant crop plants in collaboration with plant physiologists. Experimentation would involve annuals as well as perennial horticultural species.

Qualifications:

A Ph.D. degree in plant breeding and genetics, or equivalent qualifications.

Salary:

Research Scientist or Senior Research Scientist: \$A14,829 to \$A21,543 p.a.

Tenure:

Either: (i) an indefinite appointment as Research Scientist; or (ii) a fixed-term appointment as Postdoctoral Research Fellow, may be negotiated. Both carry Superannuation benefits.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 491/49 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
Canberra House,
Maltravers Street,
LONDON
WC2R 3EH,

by 4th NOVEMBER 1978.

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific),
Embassy of Australia,
1601 Massachusetts Avenue, N.W.,
WASHINGTON D.C. 20036,
U.S.A.

7378(A)

NEW ZEALAND
Ministry of Agriculture and Fisheries

SCIENTIST

Levin Horticultural Research Centre
(Vacancy No. 5560)

Salary payable depending on qualifications and experience, up to N.Z. Dirs19642 p.a.

DUTIES:

A permanent position is available in the Ornamentals and Glasshouse Section for applied Research on Food or Ornamental Crop Production.

QUALIFICATIONS REQUIRED:

An honours degree or a higher degree in Horticulture or Science with experience in research, extension or commercial production of either Greenhouse or Nursery Crops, together with proven ability in research, communication and co-operation in a small research team.

SCIENTIST

Hastings Horticultural Research Station
(Vacancy No. 5559)

Salary payable depending on qualifications and experience up to N.Z. Dirs19642 p.a.

DUTIES:

Officer in charge, responsible for the Ministry's Research Programme on Crops for processing in the Hastings District.

QUALIFICATIONS:

Honours degree or Phd in Horticulture, Agriculture or Plant Science.

Passages and Incidental Expenses. Consideration may be given to providing assistance with passages and incidental expenses.

Applications with full details of age, experience and family should be sent to:—

The Chief Migration Officer,
New Zealand House,
Haymarket,
LONDON SW1Y 4TQ

You should quote reference Imm 2/320/15 and the Vacancy number in your application.

Closing date for application 17th November, 1978.

7336(A)

SOUTH GLAMORGAN HEALTH AUTHORITY (T)
UNIVERSITY HOSPITAL OF WALES

SCIENTIFIC OFFICER

DEPARTMENT OF HAEMATOLOGY

A graduate is required to take part in the biochemical investigation of abnormalities in iron metabolism and erythropoiesis. Duties will include the use of spectrophotometric, atomic absorption and immunoradiometric assay techniques. The person to be appointed should have an interest in developing a career in hospital laboratory medicine.

The appointment is on the Basic Grade Scientific Officer scale £2,991 to £4,899.

Application forms from: Personnel Department, University Hospital of Wales, Heath Park, Cardiff. Tel: 0222 755944.

Further particulars may be obtained from: Mr B. Jones, Department of Haematology, University Hospital of Wales, Heath Park, Cardiff. Tel. (0222) 755944 ext. 2372. Closing Date: October 20, 1978.

7361(A)

ST GEORGE'S HOSPITAL
MEDICAL SCHOOL
(University of London)
TECHNICIAN 5

Experienced Technician 5 required to work mainly as personal assistant to Professor P. N. Dilly, Department of Structural Biology, without close supervision in all aspects of the fields of transmission and scanning electron microscopy and photography. A knowledge of histological techniques would be an advantage. Emoluments range £3,461 to £3,995 per annum. Application forms available from the Establishment Officer, St. George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.

7334(A)

THE UNIVERSITY OF
PAPUA NEW GUINEA
(Port Moresby)

Applications are invited for the post of LECTURER IN PHYSIOLOGY in the DEPARTMENT OF HUMAN BIOLOGY tenable from January 1979. The Department of Human Biology teaches preclinical basic medical sciences to second and third year medical students. The Department teaches an integrated programme of courses comprising human structure, physiology and neurophysiology, biochemistry and pharmacology. Applicants should have a higher degree in science or medicine and have experience in teaching physiology to medical students. Experience in teaching in a developing country would be an advantage. Salary: Lecturer K9,048 to K14,218 per annum (£1 Sterling equals K1.35). In addition, an allowance of K1,300 if single is payable. An extra K1,000 Marriage Allowance and K156 per child Child Allowance may also be payable. Conditions include provision of housing; annual leave fares; study leave and F.S.S.U. In some cases it may be possible to make an appointment on secondment. Detailed applications (two copies) with curriculum vitae and also naming three referees, with a small photograph, to be sent direct to the Secretary, University of Papua New Guinea, Box 4820, Papua New Guinea by November 3, 1978. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

7335(A)

LONDON SCHOOL OF
HYGIENE AND
TROPICAL MEDICINE
(University of London)

Keppel Street, WC1E 7HT
CLINICAL NUTRITION AND
METABOLISM UNIT
4 St Pancras Way, NW1 2PE
A MEDICAL LABORATORY
SCIENTIFIC OFFICER

is required up to September 30, 1981 to work on the regulation of protein synthesis and breakdown in rats and man. Candidates should preferably be graduates in biochemistry or hold equivalent qualifications. Inclusive salary, depending on qualifications and experience, rises to a maximum of £4,284. Applications, consisting of full career and education details and naming two referees, should be sent to Dr P. J. Garlick at the Unit.

7332(A)

LONDON SCHOOL OF
HYGIENE AND
TROPICAL MEDICINE
(University of London)

Keppel Street, WC1E 7HT
DEPARTMENT OF
MEDICAL PROTOZOLOGY
LECTURESHIP

A new post has been created for the study of the immunology of protozoal infections of mucous surfaces. Applications are invited from suitably qualified candidates.

The person appointed will be expected to participate in the general teaching of the Department and the supervision of higher degree students as well as to undertake an active research programme. An ability to attract outside support for the research work will be an advantage. Salary will be on the "interim" scale for lecturers, ranging from £3,883 to £7,754 plus £450 London Allowance. Further details of the appointment may be obtained from Professor W. H. R. Lumsden. Application forms may be obtained from the Dean at the School and should be returned to him by November 16, 1978.

7333(A)

QUEEN MARY COLLEGE
(University of London)
DEPARTMENT OF PLANT
BIOLOGY AND MICROBIOLOGY
A Grade 3 and a Grade 5
TEACHING/RESEARCH
TECHNICIAN

required to work in a Molecular Genetics group headed by Professor E. A. Bevan. The main research interests of the group are concerned with viral infections and cytoplasmic organelle genetics in yeast. The teaching duties involve assisting in the preparation of laboratory classes, especially those dealing with aspects of Microbial and Molecular Genetics. Some experience in handling micro-organisms, biochemical separation including ultra-centrifugation techniques, would be useful.

Minimum qualifications, Grade 3 O.N.C. and Grade H.N.C. or equivalent. Salary scales £2,688 to £3,060 per annum and £3,186 to £3,720 per annum respectively and in both cases plus £465 per annum London Weighting. 5-day week, 4 weeks annual leave plus a week at Christmas and Easter which includes the public holidays.

Letters only to Assistant Secretary (Establishment), PB/DM, Queen Mary College, Mile End Road, London E1 4NS, stating age, experience, qualifications and which post applied for. Closing date: October 11, 1978.

7375(A)

THE BRITISH COUNCIL
INVITES APPLICATIONS FOR
THE FOLLOWING POST
TEACHER OF
SILVICULTURE
TEACHER OF BOTANY
(Iran)

Higher School of Natural Resources, Gorgan. To teach up to B.Sc. level, give practical instruction, set and mark examinations, assist with curriculum development. Degree plus postgraduate diploma or preferably M.Sc. in forestry or related subjects and at least two years' relevant teaching experience. Candidates, men only, should be single or married with a maximum of two children under five.

Salary: £5,750 to £7,048 per annum tax-free.

Benefits: Personal and children's allowances; free furnished accommodation; baggage allowance. One year contract, renewable.

Return fares are paid. Local contracts are guaranteed by the British Council. Please write briefly stating qualifications and length of appropriate experience, quoting reference number 77 HO 40 & 42, and title of post, for further details and application form to The British Council, 65 Davies Street, London W1Y 2AA.

7346(A)

THE GRASSLAND
RESEARCH INSTITUTE
Hurley, Maidenhead
Berkshire
SYSTEMS ANALYSIS
IN AGRICULTURE

The Institute is seeking an officer to develop and apply the techniques of systems analysis and mathematical modelling to biological and agricultural problems.

Applications are invited from scientists with a basic training in mathematics, statistics and computer programming or the physical sciences. Computing facilities include access to ICL 4/72 and IBM 370 machines.

The Grassland Research Institute is grant aided by the Agricultural Research Council and is associated with the University of Reading.

The appointment will be made in the Higher Scientific Officer or Senior Scientific Officer grade.

SALARY: H.S.O £4,101 to £5,488; S.S.O £3,154 to £6,898, grade and starting salary will depend on experience.

QUALIFICATIONS: A First or Upper second class honours degree or the equivalent in an appropriate subject and at least two years' relevant post-qualifying experience.

A minimum of four years' relevant post-qualifying experience is required for appointment to the S.S.O grade.

Applications to the Secretary with curricula vitae and the names of three referees by October 27, 1978.

7376(A)

WELSH NATIONAL SCHOOL
OF MEDICINE
(University of Wales)
K.R.U.F. INSTITUTE OF
RENAL DISEASE
CARDIFF ROYAL INFIRMARY
SEROLOGIST/
IMMUNOLOGIST

required for a 2-year appointment funded by the M.R.C., to study antibodies in kidney transplant patients. Knowledge of tissue typing techniques would be an advantage.

Commencing salary could be up to £4,631 per annum for suitably qualified applicants.

Application forms available from the Registrar and Secretary, Welsh National School of Medicine, Health Park, Cardiff (quoting Ref. No M6/7/14). Further information available from Mr J. Salaman, F.R.C.S (Tel: Cardiff 492233.) 7365(A)

UNIVERSITY OF SYDNEY
LECTURESHIP IN
VETERINARY PATHOLOGY

Appointee to be responsible for teaching research and diagnostic services in the field of Veterinary Clinical Pathology and will be located in Sydney Veterinary qualifications or equivalent required. Experience in clinical or practical pathology desirable.

The position may be filled either on a tenured basis, or in the first instance, for a probationary period of three years with the possibility of tenure being given during or shortly after that period, or in certain cases return fares.

Salary Range: \$A15,179 to \$A19,940 per annum.

Applications including curriculum vitae, list of publications and names of three referees by October 31, 1978 to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Apsu), 36 Gordon Square, London WC1H 0PF. 7353(A)

CSIRO AUSTRALIA Research Scientist Division of Building Research Hihett, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,200 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Microbiology/Mycology

Duties:

To form part of the Division's multidisciplinary Conservation and Biodegradation Section by conducting research on both fundamental and applied levels into the fungal decay of preservative-treated and untreated wood and other diverse structural materials. The work includes the development of control mechanisms, chemical, physical or biological; the physiology and ecology of biodeteriogens and their mechanisms of degradation; and some fungal taxonomy. The candidate should have a sound mycological training and background, and will be expected to work both as an individual researcher and as a member of a research team.

Qualifications:

A PhD degree in mycology/microbiology, agricultural science, biochemistry, or other relevant discipline and previous research ability. Preferably the applicant should possess a sound working knowledge of biochemistry as an addition to his major area or expertise in mycology.

Salary:

Research Scientist or Senior Research Scientist: \$A14,829—\$A21,543 p.a.

Tenure:

Indefinite with superannuation.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 390/627 should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
Canberra House,
Maltravers Street,
LONDON WC2R 3EH

by 4th November 1978.

Applications in U.S.A. and Canada should be sent to:—

The Counsellor (Scientific),
Embassy of Australia,
1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C., 20036, U.S.A.

7377(A)

AWARDS

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF BIOCHEMISTRY

S.R.C. C.A.S.E AWARD

"Sillcos and related materials as beer stabilisers".

Cooperating Body. Unilever Research, Port Sunlight.

Applications are invited from suitably qualified biochemists and chemists by November 20, to Professor J. S. Hough, Biochemistry Department, The University, P.O. Box 363, Birmingham B15 2TT. Commencement date in 1979 is subject to discussion. 7288(N)

M.R.C. CLINICAL RESEARCH CENTRE (Northwick Park Hospital)

Watford Road, Harrow, Middx. HA1 3UJ

The Division of Immunological Medicine (Head Dr. G.L. Asherson) require a medical or recent post-doctoral person interested in studying the cellular defects in immune deficiency disease and in particular hypogammaglobulinaemia. The appointment is for three years only and the salary is on NHS registrar/sen. reg. scale or on university lecturer scale depending upon qualifications.

Application form obtainable from Mrs. J. Tucker-Bell by October 21st. Please quote ref. 118/1/4209. 7339(A)

THE OPEN UNIVERSITY

Lecturers in Science Biology

We have two vacancies: those appointed will be involved in the preparation and maintenance of the discipline's 2nd and 3rd level courses in one or more of the areas of Ecology, Mammalian Physiology, and Molecular Biology/Biochemistry. They will also be expected to take an active interest in the development of the discipline's future offerings in the field of continuing education, and to undertake research—either independently, or with one of the existing research groups. For these posts, candidates are likely to be under 30, with teaching experience and a good research record.

Ref: 3662

Earth Sciences

We have two vacancies: the successful applicants will take part in the remaking of the 2nd level courses in Geology or the Earth's Physical Resources, and may have research interests in any branch of the discipline. They will be expected to pursue those research interests vigorously.

Ref: 3663

Physics

There is one vacancy in this discipline: the person appointed will assist in the preparation of appropriate undergraduate courses, using multi-media teaching methods, and will also be expected to undertake research—either independently or with colleagues.

Ref: 3660

Applicants for all posts should be able to demonstrate an ability to write clearly and easily and an interest in distance teaching. All five posts are tenured: salary will be on the scale £3,883—£7,754 (under review and there are U.S.A. and other benefits).

Application forms and further particulars are available, by postcard request please, from The Recruitment Office (JD3663/00), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL, or telephone Milton Keynes 63868: 24 hour answering service.

PLEASE STATE THE DISCIPLINE IN WHICH YOU ARE INTERESTED

Closing date for applications: 20th October 1978. 7315(A)

FORTH RIVER PURIFICATION BOARD

PHYSICAL OCEANOGRAPHER

Applications are invited for the post of Physical Oceanographer with the Board's Estuary Survey Section.

The successful applicant will join a small team of specialists working on water quality problems within the Firth of Forth. Ideally candidates should have a sufficient understanding of numerical analysis and estuarine processes to be able to improve the Board's existing steady state model and to develop a time varying model of the Forth Estuary. The Forth Estuary is of particular interest as it demonstrates many of the transient features associated with a partially mixed estuary. Facilities include direct access, via a terminal, to 2M bytes of core store on a local University computer system and use of the Board's 60 foot survey vessel. Apart from modelling studies, duties will include involvement in surveys of outfall sites and the hydrography of inshore areas.

The post is superannuable and subject to N.J.C. conditions of service. Salary will be in the range £4,368 to £5,403 inclusive of £312 supplement, with placing according to age, qualifications and experience.

Applications should include the names of two referees and be submitted not later than Friday, October 20, to:

The River Inspector,
Colinton Dell House,
West Mill Road,
EDINBURGH EH13 0PH.

7308(A)

MEDICAL RESEARCH COUNCIL ELECTRON MICROSCOPIST

Applications are invited from graduates with a degree in Medicine, or Biological Sciences to develop a research programme into the mechanism of action of toxic substances. The successful candidate will be responsible for leading a group consisting of one other scientist (to be appointed) and two technicians together with research students and visiting scientists. He will also be responsible for promoting collaborative research with other members of the unit working Toxicological problems, either in the whole animal or in isolated cells cultured *in vitro*.

Salary on M.R.C. scientific staff scales (non-clinical) depending on age and experience.

Apply in writing enclosing a full curriculum vitae and giving the name of two referees to the Director, Toxicology Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

MRC
Medical Research Council

7272(A)

COMMONWEALTH AGRICULTURAL BUREAUX Vacancy for SCIENTIFIC INFORMATION OFFICER at the COMMONWEALTH INSTITUTE OF ENTOMOLOGY 56 Queen's Gate, London SW7 5JR

Duties: Mainly preparing abstracts in English for the journal 'Review of Applied Entomology' which covers the world of scientific literature on injurious and useful insects. Either one full-time or two part-time appointments would be considered.

Qualifications: Graduate required with ability to read Russian or German and preferably some knowledge of biology or agriculture; knowledge of other Slavonic or of Scandinavian languages would also be useful. The ability to write good, concise English is essential.

Salary: In the scale £2,839 to £5,448 per annum plus Inner London Weighting of £465 per annum, plus a compensatory allowance (taxable but not superannuable) of 3.3 per cent to offset personal contribution to Superannuation Scheme; part-time appointments pro-rata. Starting salary according to qualifications, experience and age.

Application forms and full particulars from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN, to whom completed applications (in duplicate) should be sent by October 28, 1978.

7318(A)

ST. THOMAS' HEALTH DISTRICT (TEACHING) London SE1 MEDICAL LABORATORY SCIENTIFIC OFFICER (Grade subject to qualifications and experience) DEPARTMENT OF CHEMICAL PATHOLOGY AND METABOLIC DISORDERS ST. THOMAS' HOSPITAL

A post is available in the Supra Regional Hormones Laboratory, which will involve work on both protein and steroid hormones. Previous experience in radioimmunoassay would be an advantage, but is not essential.

The successful candidate will have the opportunity of pursuing further relevant qualifications.

For application form and job description, contact Ms J. Frost, Personnel Officer, St. Thomas' Hospital, London SE1 7EH, quoting ref. SRHL. Closing date October 20, 1978.

7289(A)

BIOCHEMIST—MOLECULAR BIOLOGIST

The Department of Biological Sciences, Carnegie-Mellon University invites applications from molecular biologists whose research interests lie in the area of nucleic acid structure and/or function. Candidates should have postdoctoral experience. The position is at the assistant professor level, although higher appointments will be considered. Duties include teaching at the undergraduate and graduate level as well as maintaining an active research programme. Applicants should forward their curriculum vitae, three or more letters of reference and a brief résumé of research plans to Search Committee (2), Department of Biological Sciences, Carnegie-Mellon University, 4400 Fifth Ave., Pittsburgh, PA 15213. *Carnegie-Mellon University is an Equal Opportunity/Affirmative Action Employer.*

7349(A)

INSTITUTE OF ORTHOPAEDICS (University of London), Research Assistant, Honours Graduate in Biology to participate in research into human hip disease. Suitable for M.Phil./Ph.D. Three year Arthritis and Rheumatism Council grant. Information from and applications to the Secretary, Institute of Orthopaedics, Brockley Hill, Stanmore, Middlesex HA7 4LP, with two referees.

7309(A)

POSITION OPEN

A postdoctoral position is available for a period of one to three years to study mechanisms of action of peptides (substance P, somatostatin, endorphins) in mammalian spinal pain pathways using predominantly electrophysiological techniques. Send curriculum vitae and three references by January 1, 1979 to M. Randic, Department of Veterinary Anatomy, Pharmacology and Physiology, Iowa State University of Science and Technology, Ames, Iowa 50011. An Affirmative Action/Equal Opportunity Employer.

7350(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR TECHNICIAN GRADE 4

£2,955 to £3,402 per annum

Applications are invited for the post of Histology Technician in the Department of Zoology.

The main duties will be the preparation and sectioning of material for examination in the light microscope together with some assistance in the laboratories.

Qualifications required are O.N.C. or an equivalent qualification.

Applications (two copies), giving details of age, education and experience, together with the names and addresses of two referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, by not later than October 16, 1978.

7358(A)

TECHNICIAN GRADE 2B

required for the teaching laboratories of the Biophysics Department. This is an interesting post concerned with the teaching of a wide range of courses. Other duties include help with the annual unit and helping academic staff with research. Salary on scale £2,994 per annum rising to £3,345 per annum inclusive. Four weeks annual holiday. College contributory pension scheme. Apply in writing with full details to: The Head Clerk, King's College London, Strand, WC2R 2LS. Ref. 204016/N. 7283(A)

QUEEN ELIZABETH COLLEGE

Kensington

(University of London)

GRADE IV RESEARCH

TECHNICIAN

Required to maintain and operate a Kratos AEI MS25/DS508 gas chromatograph-mass spectrometer with computer data processing. This new instrument will provide a GC/MS service under the University of London Inter-collegiate Research Service, and will specialise in capillary column GC and chemical ionisation MS. The unit at Q.E.C. already possesses an MS30/DS50 and the successful candidate will be expected to operate this instrument as well, and to carry out duties assigned by the Technician in charge of the unit. Experience in mass spectrometry is desirable but not essential and necessary on-site training is available.

Salary within range £3,420 to £3,567, inclusive of London Allowance.

For application forms contact Mrs G. M. Howard, Tel. 01-937 5411, Ext. 499, Queen Elizabeth College, Campden Hill Road, London W8 7AH. 7284(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London)

RESEARCH ASSISTANT

A group engaged in research on the metabolism and functions of endogenous peptides and steroids concerned with the control of blood vessels and of water and electrolyte metabolism requires a graduate in chemistry, biochemistry, medicine or related fields. The work, involving organ perfusions, enzyme assays and radioimmunoassays, will be suitable for a higher degree thesis. Starting salary £3,663 per annum inclusive of London Allowance. Applications with full curriculum vitae and names and addresses of two referees should be sent by October 26, to Dr J. D. H. Slater, Institute of Clinical Science, The Middlesex Hospital Medical School, London W1P 7PN. 7285(A)

CHAIR OF GEOLOGY

Applications are invited for a further Chair of Geology which is to be established during the academic year 1978/79. Salary within the professional range. Applicants may have teaching and research interests in any field of study appropriate to a University Department of Geology. Further particulars may be obtained from the Secretary and Registrar, The University, Southampton SO9 5NH, and applications (10 copies from applicants in the United Kingdom) must be submitted before November 5, 1978. 7293(A)

CSIRO

AUSTRALIA

Research Scientist or Post Doctoral

Research Fellow

Division of Fisheries & Oceanography

Perth, Western Australia

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Biological Oceanography

General:

The Division is Australia's principal marine research institution with about 70 scientists investigating the physical, chemical and biological features including fisheries of the oceans around Australia. Headquarters of the Divisions are at Cronulla, Sydney, with regional laboratories in Perth, Brisbane and a field laboratory in Karumba. On-line access to a Cyber 76 computer is available. Two well-equipped medium sized chartered vessels are available for oceanographical research and there are several smaller CSIRO vessels.

Duties:

To initiate and carry out research in coastal marine ecology, as part of a research team investigating the production kinetics of a limestone reef.

Qualifications:

Marine ecologist with experience in community ecology of reef ecosystems. Some special knowledge of nutrient cycling and fisheries within such systems would be an advantage. Minimum qualifications are a Ph.D. or equivalent qualification in a relevant field of marine biological research, together with appropriate postdoctoral experience.

Salary:

Dependent upon experience within the ranges: Research Scientist: \$A14,829 — \$A18,177 p.a. or Senior Research Scientist: \$A18,819 — \$A21,543 p.a.

Tenure:

An indefinite appointment or a fixed-term appointment of 3 to 5 years may be negotiated. Both carry Superannuation benefits.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 320/604 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH. by 4th November 1978.

Applications in U.S.A. and Canada should be sent to:—

The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., WASHINGTON, D.C., 20036, U.S.A. 7379(A)

Careers in Drug Metabolism Greenford, Middlesex

Two vacancies have arisen in our laboratories for appropriately qualified scientists to be responsible for the development and use of analytical procedures for measuring drug levels in biological materials.

The work is concerned with the study of the absorption, distribution and metabolism of existing and new therapeutic agents. One of the above vacancies would suit a graduate with two to three years relevant experience, possibly with a post-graduate qualification, although this is not essential. The second vacancy would be suitable for a person who has recently qualified. In both cases candidates should hold good first degrees in relevant scientific disciplines and have an interest in bio-analytical methods.

The Company offers excellent conditions of employment including pension and bonus schemes, subsidised cafeteria and a sports and social club.

Please write or telephone for an application form to:

Miss E. M. Butler
Secretary to Senior Personnel Officer
Glaxo-Allenburys Research (Greenford) Limited
Greenford, Middlesex.
Quoting Ref. 241
01-422 3434, Ext. 11

Glaxo-Allenburys Research (Greenford) Limited

Director of Research

A major French pharmaceutical group is looking for a top-flight scientist, with biological, medical and pharmaceutical qualifications. To be located in Paris, the director of research will be entrusted with determining, in co-ordination with the general management, the group's research policy with the application of that policy and with participating in general policy decisions, including licensing to other groups.

Salary will be in accordance with qualifications and with the position offered.

Please send CV, recent photograph and current salary under ref. 1054 N.

All applications will be treated with the highest confidentiality by:

BERNARD KRIEF CONSULTANTS

1, rue Danton 75263 Paris Cedex 06

Simon Fraser University

DIRECTOR MASTER OF NATURAL RESOURCE MANAGE- MENT PROGRAM

A Director is required for the Master of Natural Resource Management Program which has been established at Simon Fraser University. The new program, which will admit its first students in September, 1979, consists of two years of graduate work, and is designed for recent graduates and experienced professionals. The Director will co-ordinate instructional and research programs from varied disciplines and departments.

The Director should have an established academic and professional reputation in one of the disciplines related to resource management and will be offered a permanent appointment jointly between the program and an appropriate department.

The preferred date of appointment is January, 1979, but later starting dates can be negotiated. Salary and rank will be dependent upon qualifications. Applicants should send curriculum vitae and the names of three referees to:

Dr T. W. Calvert

Dean,
Faculty of Interdisciplinary Studies,
SIMON FRASER UNIVERSITY
Burnaby, B.C., Canada
V5A 1S6 7312(A)

UNIVERSITY OF BRISTOL DEPARTMENT OF CHILD HEALTH RESEARCH ASSISTANT

Postdoctoral scientist or equivalent with experience in electron microscopy, immunology and/or autoradiography to work on immediate hypersensitivity in the lung. Starting salary up to £4,382 per annum. Applications with a curriculum vitae and two referees to Dr F. Carswell, from whom further information obtainable, Department of Child Health, Children's Hospital, Bristol BS2 8BJ.

7310(A)

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales) DEPARTMENT OF HAEMATOLOGY RESEARCH OFFICER

A graduate in biological or natural science is required to take part in an investigation of blood cell formation in haematological disorders.

The study involves analysis of the kinetics of iron metabolism and a knowledge of mathematics/computing would be an advantage.

The appointment is for two years and will be made on the Research and Analogous Staff Scale IB, £3,384 to £4,882 (under review).

Further particulars may be obtained from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, to whom applications, in the form of a brief curriculum vitae with the names and addresses of two referees, should be submitted within two weeks of the date of this advertisement, quoting Ref. No H24/2/21. The Department may be visited by arrangement with Dr I. Cavill (0222 755944, extension 2365) 7366(A)

IMPERIAL COLLEGE FIELD STATION ZOOLOGY DEPARTMENT

A Research Assistant is required for an A.R.C.-sponsored project on movement and metabolism of systemic pesticides in relation to plant-parasitic nematodes. The work will involve use of radiotracer techniques and maintenance of experimental plants in controlled environmental conditions. Experience of work with nematodes is not essential. Salary in the IB range £3,384 to £4,882 per annum, plus U.S.S.

Applications stating age, qualifications, experience and names and addresses of two referees to: Dr D. J. Wright, Imperial College Field Station, Sunninghill, Ascot, Berkshire, from whom further details may be obtained 7352(A)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

Applications are invited for the post of postdoctoral Senior Research Assistant to work in a multi-disciplinary team studying drugs used in tropical diseases. The work will involve quantification, chemical synthesis and structural determination of drug metabolites.

The project is financed for up to three years, and the initial salary will be in the range £3,883 to £4,631 per annum.

Applications, together with the names of two referees, should be received not later than October 20, 1978, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/941/N. 7287(A)

UNIVERSITY COLLEGE LONDON DEPARTMENT OF PHYSIOLOGY LABORATORY TECHNICIAN GRADE 3

A vacancy exists for a laboratory technician to work with a small group investigating the relation between mechanical and biochemical events in muscle fibres. Starting salary £2,684 to £2,760 plus £465 London Weighting. Supported by a five-year grant from the M.R.C. Application form from Personnel Officer (Technical Staff FF4), University College London, Gower Street, WC1E 6BT.

7355(A)

FELLOWSHIPS—(continued on page xxiv)

IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

A Postdoctoral Fellow required as soon as possible for an appointment of two years with possible extension to three years. The work will be on the mechanisms by which host cells control the expression of tumour-inducing viruses. Familiarity with nucleic acid hybridisation and allied techniques would be an advantage but is not essential. Salary with entry according to qualifications and experience within range £4,815 to £6,180 inclusive.

Applications with curriculum vitae and names of two referees, should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by November 3, 1978, quoting reference 294/78.

7297(E)

RAMSAY MEMORIAL FELLOWSHIP FOR CHEMICAL RESEARCH.

The Trustees will consider in February 1979 applications for a British (General) Fellowship, normally tenable in the United Kingdom for two years, for candidates with experience of postdoctoral research. Value of the Fellowship will normally be parallel with lower part of Lecturer scale for British Universities, plus expenses grant of up to £100 per annum. May be superannuable. The person elected will normally be required to take up the Fellowship on or about October 1, 1979. Particulars from Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College London, Gower Street, London WC1E 6BT. Completed application forms must be received by December 1, 1978.

7316(E)

A POSTDOCTORAL FELLOWSHIP

is now available to study the mechanism of benzene toxicity. Current investigations are aimed at understanding the relationship between the hematological/bone marrow effects of benzene and benzene metabolism (see Life Sci. 21, 1709, 1977). This is an opportunity to train in biochemical toxicology. The stipend is \$10,000.

Interested parties should write to Dr Robert Snyder, Dept. of Pharmacology, Thomas Jefferson University, Philadelphia, Pa., U.S.A. 19107. 7369(E)

UNIVERSITY OF BRISTOL POSTDOCTORATE RESEARCH FELLOWSHIP

Applications are invited for a post-doctorate fellowship established to investigate the synaptic mechanisms regulating the peptidergic neurones of the magnocellular nuclei of the rat hypothalamus. Previous experience of electrophysiological recording from the CNS is required, and some expertise in the application of iontophoretic methods is desirable.

The appointment is funded by the Medical Research Council for two years from October 1, 1978. Salary will be determined by age and experience (minimum £4,382 per annum at age 26—scale under review).

Applications giving details of age, qualifications and experience, together with the names of two referees, should be sent by October 16 to Dr D. W. Lincoln, The Medical School, University Walk, Bristol BS8 1TD, from whom further particulars are available (Bristol 24161, ext. 557).

7241(E)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF GEOLOGICAL SCIENCES RESEARCH FELLOWSHIP— STABLE ISOTOPES IN GROUNDWATER

Applications are invited for the above post to carry out the measurement and interpretation of the stable isotopes of oxygen and deuterium in precipitation in the soil profile and in modern groundwaters. The work is supported by a research grant from the Natural Environmental Research Council.

Applicants should have a good honours degree in either Geology, Chemistry or Physics and preferably a Ph.D. Research experience related to isotope studies would be an advantage.

Salary in the range £3,883 to £6,555, plus superannuation. The starting point will be dependent on age and experience, with a maximum of £4,382. The post is tenable until September 30, 1981. Further particulars may be obtained from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae, and naming three referees should be sent by Monday, October 23, 1978. Please quote ref: NG9.

7356(E)

POSTDOCTORAL FELLOWSHIP

The laboratory is engaged in full-time research (primarily biochemical) on the structure and function of microtubules (see J. Cell Biol. 73, 492 and Biochemistry 16, 2189). The candidate must have received the doctor's degree within three years, and may not be a citizen of the U.S.A. Enquiries, accompanied by a curriculum vitae and references, should be sent to: Dr Martin Flavin, Lab. of Cell Biology, NHLBI, National Institutes of Health, Bethesda, Md. 20014, USA.

7294(E)

THE UNIVERSITY OF BIRMINGHAM DEPARTMENT OF PHYSIOLOGY RESEARCH FELLOWSHIP

Applications are invited for a Research Fellowship working on a five year M.R.C.-funded project in the Department of Physiology. Applicants should have a degree in Science or Medicine and experience in Neurophysiological Research. The Fellow will study motor control in man and primates by methods that involve the application of engineering methods to physiological systems. The project is directed by Dr P. M. H. Rack from whom further information may be obtained.

Salary will be on the Research Scale 1A (£3,883 to £6,555 plus superannuation) according to age and experience. The appointment will date from January 1, 1979 or as soon thereafter as may be arranged.

Applications with curriculum vitae and names of two referees should be sent to the Assistant Registrar, The Medical School, Birmingham B15 2TT by November 24, 1978. Please quote reference RF/Phy/378.

7291(E)

POSITIONS WANTED

BIOCHEMISTRY TECHNOLOGIST, A.I.M.L.S.

25, with excellent academic record, seeks position in continental Europe, Australasia or North America. Prefer non-clinical field (e.g. research, industrial, publishing). Box No. 7265(B), c/o Macmillan Journals Ltd., 3 Dyers Buildings, London EC1N 2NR.

7265(B)

UNIVERSITY OF AUCKLAND NEW ZEALAND UNIVERSITY POSTDOCTORAL FELLOWSHIPS 1979/1980 AWARDS

Applications are invited for Fellowships to begin during the period March 1, 1979, to February 28, 1980. The Fellowships are awarded for the purpose of carrying out advanced research. Successful applicants may be expected to participate in limited teaching activities. Conditions of Appointment and application forms to be completed by candidates are available from New Zealand and Australian universities, from the Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand, or from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications will be accepted at any time up to **OCTOBER 31, 1978.**

The Fellowships are open to graduates of universities other than the University of Auckland; and holders of a Bachelors or Masters degree from the University of Auckland who have also completed a Ph.D. degree at any university other than the University of Auckland. Prospective candidates should note that these Fellowships are NOT open to applicants whose Ph.D. degree was completed at the University of Auckland. To be eligible for a Fellowship, candidates must have been awarded the degree of Doctor of Philosophy, or have completed the requirements for such an award, or hold some other appropriate academic qualification. The Awards are primarily intended for candidates who have held a Ph.D. for not more than four years at the time of application, but in exceptional circumstances other candidates may be considered. The total value of the Fellowships will normally be based on a monthly allowance of NZ\$700 plus, where applicable, actual approved fares for the Fellow only. Fellows should expect to pay tax on the monthly allowance.

The Fellowships are tenable for up to 12 months and have been allocated to the following research groups. Prospective candidates seeking further information should write directly to the member of staff named in the University.

Anthropology (Professor R. C. Green). Topic: Melanesian cultural history programme. Candidates in ethnohistory, historical linguistics, ethnobotany or applied science in archaeology.

Anthropology (Associate-Professor A. Hooper). Topic: Tokelau studies. Biochemistry (Professor A. G. C. Renwick). Topic: The biochemistry of glycoprotein hormone receptor interactions.

Cell Biology (Professor R. E. F. Matthews). Topic: Plant virology.

Cell Biology (Dr H. E. D. Lane/Professor P. L. Bergquist). Topic: Plasmid-specified proteins in *E. coli* minicells.

Chemistry (Professor R. C. Cambie). Topic: The utilisation of New Zealand natural products.

English (Associate-Professor MacD. P. Jackson). Topic: New Zealand literature.

Electrical Engineering—Radio Research Centre (Professor H. A. Whale). Topic: Ionospheric propagation, upper atmosphere physics and communications research.

History (Professor P. N. Tarling). Topic: National-international linkages in military occupation and post independence administration, planning and development in East and South East Asia.

History (Professor M. P. K. Sorrenson). Topic: Social, economic and political history of New Zealand.

Mathematics (Professor J. C. Butcher). Topic: Numerical solution of ordinary differential equations.

Physics (Professor A. R. Poletti). Topic: Experimental nuclear physics.

Psychology (Professor M. C. Corballis). Topic: Cognitive psychology.

Zoology (Dr B. A. Foster). Topic: Settlement and recruitment of the larvae of marine animals.

7364(E)

CYSTIC FIBROSIS RESEARCH FELLOWSHIPS

The Cystic Fibrosis Research Trust is anxious to encourage research into the problems of Cystic Fibrosis by offering special grants to medical and scientific departments and to establish Fellowships in this area of research. The Trustees would be specially interested in supporting a Fellowship in a suitable department to an individual with considerable research training especially in fields likely to lead to further knowledge of the basic abnormality in this condition. The Fellowship would ordinarily be held for three years and applications must be sponsored by the Head of the department who would be willing to provide facilities. In the first instance twelve copies of a two-page summary of the proposal should be provided, together with a curriculum vitae, a brief estimate of the anticipated costs of the Fellowship, apart from salary, should be indicated.

Applications should be addressed to Mr R. Tucker, Executive Director, C.F. Research Trust, 5 Blyth Road, Bromley, Kent BR1 3RS. Closing date: November 30, 1978.

7371(E)

FELLOWSHIPS

BRITISH/IRANIAN
SCIENTIFIC EXCHANGE
SCHEME

To stimulate Irano/British collaboration in science and technology, the Iranian Ministry of Science and Higher Education and the British Council have launched an exchange scheme, which began in April 1977. British visitors, ideally science or technologists with active research programmes established in a research institution, will spend between one and ten months participating in research or field studies, or exploring prospects for co-operative work with Iranian colleagues. Applicants who already have contacts with Iran will be given preference. The closing date for this year will be December 31. For further details and an application form, please write or telephone to Dr J. C. Viney, Higher Education and Science Department, the British Council, 10 Spring Gardens, London SW1A 2BN (telephone 01-930 8466, extension 2609). 7298(T)

For those who are seeking a change in their careers we now offer this new service...

APPOINTMENTS WANTED

will appear weekly; the advertising charges are £1.50 or \$3.00 per line (approximately seven words). Minimum 3 lines. Box numbers are automatically given without further charge, all correspondence to: NATURE CLASSIFIED

London Office:
3 DYERS BUILDINGS,
LONDON, EC1N 2NR
Telephone: 01-831 6901

Washington Office:

Telephone: (202) 737 2355

SYMPOSIA

A Symposium on "Long-term
effects of Neuroleptics"

will be held in Monte-Carlo, Principauté de Monaco, March 18-21, 1979. Details from F. Cattabeni, G. Racagni and P. F. Spano, International Menarini Foundation — Piazza del Carmine, 4 — 20121 Milan (Italy). 7382 (M)

ROYAL SOCIETY
OF MEDICINE
1 Wimpole Street,
London W1M 8AE

The Section of Pathology of the Royal Society of Medicine has organised a two-day international Symposium entitled: QUANTITATIVE CYTOCHEMISTRY AND ITS APPLICATIONS for November 13 and 14, 1978.

Papers will be given under the following headings: Nucleic acid cytophotometry and Pathology; Haematology and Immunology; Toxicology and Pharmacology; Dermatology; Connective tissue disease; Maturation of the Graafian follicle; Cancer diagnosis and Research; and the Bioassay of Polypeptide Hormones.

Details of the programme and application forms may be obtained from the Sections Officer at 1 Wimpole Street (Telephone: 01-580 2070).

Closing date: November 1, 1978. 7330(M)

PERSONAL

RAPPORT is the discerning person's way of meeting new friends. Whatever your age, location or preferences, enrich your quality of life immeasurably with RAPPORT, the intelligent person's introduction service—and rediscover the joy of living. Details from RAPPORT, P.O. Box 94, Oxford. 7325(R)

LECTURES

The social and safety implications
of
Genetic engineering

A one-day public meeting organised by the Association of Scientific, Technical and Managerial Staffs, Friday, October 27, at The Pharmaceutical Society, 1 Lambeth High Street, London SE1.

The conference is open to all who wish to attend. Discussion will include not only the possible benefits and hazards of genetic engineering but also the question of reconciling public opinion and concern about safety, with the scientific and industrial progress in an increasingly technological world.

Speakers include: The Rt Hon Shirley Williams, Sir Gordon Wolstenholme, Clive Jenkins, Dr Sydney Brenner, Dr Jonathan King and Prof Bob Williamson.

For registration, which costs £4, please contact Donna Haber, ASTMS, Sutton House, 2-4 Homerton High Street, London E9 6JT or telephone 01-985 4792. Places are limited. 7374(K)

SCHOLARSHIPS

THE ROYAL SOCIETY
THE RUTHERFORD
SCHOLARSHIP

This award, for graduates of exceptional promise and ability who are under 26 years of age on May 1, 1979, is for experimental research in any branch of the natural sciences, with a preference for experimental physics if there are candidates of similar merit. It will be tenable for three years, from October 1, 1979 or such other date as may be arranged, in some part of the British Commonwealth other than that in which the applicant graduated. The value, adjusted to meet the circumstances, will be £2,250 per annum on appointment (under review) if held in the United Kingdom, with allowances for travel, university fees, etc. It will not normally be awarded to a graduate who has already held a senior research award.

Applications should be made as follows:

From university graduates in the United Kingdom: before February 15, 1979 on forms obtainable from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

From university graduates outside the United Kingdom: through their universities to the Royal Commission for the Exhibition of 1851 on forms of application for the Commissioners' Science Research Scholarship to be obtained from the registrars or administrative authorities of their universities. 7314(H)

STUDENTSHIPS

THE UNIVERSITY
OF LEEDS
DEPARTMENT OF
RADIOTHERAPY

Applications are invited from graduates with good honours degree in biological sciences for a POSTGRADUATE RESEARCH STUDENTSHIP. The project will involve a cellular kinetic and quantitative microscopical study of the action of drugs and radiation on experimental tumours.

Applications giving a full curriculum vitae, including the names and addresses of two academic referees should be forwarded to Professor C. A. F. Joslin, Regional Radiotherapy Centre, Cookridge Hospital, Leeds LS16 6QB (Telephone (0532) 673411, ext. 215), from whom further details are available. 7303(F)

STUDENTSHIPS

UNIVERSITY OF
STRATHCLYDE
DEPARTMENT OF
METALLURGY

S.R.C. C.A.S.E. Studentship

Applications are invited from candidates with a good honours degree in Physics, Chemistry or Metallurgy, or in a related discipline, for a three-year C.A.S.E. Ph.D. studentship in the Department of Metallurgy to undertake surface physics and corrosion studies of aluminium alloys using X-ray photoelectron spectroscopy, in collaboration with British Aluminium Company. The research is predominantly based at Strathclyde but the student will spend periods each year (totalling approx. four months) at the British Aluminium Research Laboratories, Chalfont, Buckinghamshire. The investigations will also include the use of synchrotron radiation with occasional periods at the S.R.C. Daresbury Laboratory Storage-Ring Facility, Warrington. S.R.C. postgraduate scales apply but additionally British Aluminium Company will consider supplementary imbursement (up to £500 per annum), with travel and accommodation expenses away from Strathclyde. Applications should be addressed to:

Dr D. J. Fabian, Department of Metallurgy, University of Strathclyde, Glasgow G1 1XN. 7304(F)

UNIVERSITY OF
EAST ANGLIA
NorwichS.R.C. CASE
STUDENTSHIP

University of East Anglia/
B.P. Chemicals Ltd.

The study of the structure of molecules absorbed on oxide catalyst surfaces by infrared and Raman spectroscopy. £1,610 plus fees.

Apply as soon as possible to Professor N. Sheppard, F.R.S., School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ. 7319(F)

UNIVERSITY OF BATH
SCHOOL OF BIOLOGY
(Animal Physiology)

Applications are invited
for an

S.R.C. STUDENTSHIP

for research on M.S.H. and related peptides in the fish pituitary.

Candidates should hold a good honours degree in Biology or Biochemistry. Enquiries and applications Dr Baker, School of Biology, The University, Bath BA2 7AY. 7328(F)

COURSES

INDIA Younger Scientists Exchange
Scheme

The British Council invites applications from suitably qualified British scientists, engineers and social scientists to visit India for up to three months under this scheme. Preference will be given to applicants who can demonstrate the applied nature of their research and an interest in developing practical collaborative projects. Successful candidates can expect to spend an extended period at one institution in India with shorter visits to one or two others.

Although applications for short periods are considered, preference is given to candidates wishing to stay for a full three months and who have already developed contacts in India. Applicants should hold a staff appointment at a university, polytechnic or research institution and are normally aged between 27 and 35 years. Return tourist class air fares will be paid and the Indian University Grants' Commission will pay an honorarium to cover expenses in India.

For visits between August 1979 and February 1980, further details and application forms are available from:

Higher Education and Science Department, The British Council, 10 Spring Gardens, London SW1A 2BN. Telephone: 01-930 8466, Ext. 2688. Closing date for applications: December 16, 1978.

Please quote AD78/4 when responding to this advertisement. 7343(J)

THE BRITISH COUNCIL
SCIENTIFIC VISITS TO THE SOVIET UNION,
CZECHOSLOVAKIA, HUNGARY, ROMANIA
AND BULGARIA

Applications are invited from British scientists, engineers and social scientists for short (two weeks) and medium term (one to six months) visits, under agreed exchange programmes, to the above countries. Short visits normally involve a tour of a number of institutions appropriate to the visitor's subject area. Medium term visits are intended to facilitate research and are usually based at one establishment.

For details and application forms please write or telephone to:

Higher Education and Science Department,
The British Council,
10 Spring Gardens,
London SW1A 2BN.
Tel: 01-930 8466, Extension 2688.

Closing date for completed applications: October 31, 1978.

Please quote 78E/4 when responding to this advertisement. 7344(J)

At Last! A Reliable Incubator Under \$100 Designed for Aerobic or Anaerobic Tissue Culture Experiments

Shown at ASM and
FASEB Meetings

Dealer inquiries invited

With this Modular Incubator Chamber, you no longer have to worry about the inherent variability (due to CO₂, temperature and humidity fluctuations) of present day continuous flow and anaerobic incubators. Simply place your experiment into the sealed chamber, purge the system with the required gas mixture and set in a controlled temperature environment.

Because each chamber is an isolated system you now have the flexibility to design experiments you previously thought were impractical or too expensive.

Chamber and tray components are made from rugged, non-toxic, uv-resistant polycarbonate.

Multi-purpose trays conveniently hold petri dishes, test tubes, T.C. flasks, microtest plates, etc.

Chambers can be stacked and interlocked for agitation or storage.

And now for the best part. The price of the chamber with 3 trays is only \$95.* To order or for further information phone or write Billups-Rothernberg, Inc., Dept. N-1, P.O. Box 977, Del Mar, CA 92014 USA (714) 755-3309.

Novel Cycloalkenopyridines

Aldrich has recently added an interesting series of 2,3-cycloalkenopyridines to its product line: 2,3-cyclopentenopyridine (1), 2,3-cyclohexenopyridine (2), 2,3-

cycloheptenopyridine (3), and 2,3-cyclododecenopyridine (4).

These cycloalkenopyridines can be metallated specifically on the side chain,¹ thus providing a general,

nonreductive route (see scheme) to the corresponding carboxylic acids (8),² esters (9),² carboxamides (10),² thiocarboxamides (6),^{2,3} and carbonitriles (7).³

Cycloalkenopyridines may exhibit physiological activity; for example, tetrahydroquinoline derivatives such as 5 are antiulcer-antisecretory agents.⁴

Gallenkamp System M furniture

THE ULTIMATE IN LABORATORY FLEXIBILITY

UNPACK

ASSEMBLE

ADAPT

SUPPLEMENT

REPLACE

Adaptability now and later with System-M

The practical answer to restrictions imposed by inflexible furniture installations.

System-M includes modular units that are freely interchangeable to meet your particular needs and can be packed flat for easy transport and storage.

Assembly of the units on site, which minimizes delay and installation costs, is simple and provides completed furniture as attractive and hardwearing as conventional designs. If you want to keep your options open contact us — we can help.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if a is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Molecular morphology of polyethylene determined by NMR	K. M. Natarajan, E. T. Samulski and R. I. Cukler	527

PHILIPS APD 10 AUTOMATIC POWDER DIFFRACTOMETRY SYSTEM

- * Automatic data processing – more information per analysis, cheaper, faster and with less risk of operator error.
- * Operates unattended, analyses up to 35 samples continuously.
- * Cuts measurement time through use of new, high-intensity tubes.
- * Stores up to 99 different measurement programmes – facilitates rapid adaptation to needs of varying analyses.
- * Easy to operate – plain-language instructions via teletypewriter keyboard.
- * Fortran programming package available for special user programmes.
- * Peak search-match on mini-file gives plain language data output of compound analyses.

...we'll hand you the answer

Linking science to technology: harder than it seems for Third World

THERE is a moral, a lesson and a set of danger signals in the three articles on science policy in Latin America in this week's *Nature* (pages 472-475). The moral is that linking a country's scientific activities to its technological needs can, in practice, be very much harder than the familiar political rhetoric would often have us believe. The lesson comes from the Andean Pact countries, who have been able to demonstrate how cooperation in research can help overcome some of the problems resulting from an over-dependence on scientific and technical skills of industrialised nations.

The danger signals relate to the increasingly important role of foreign investment—rapidly replacing the multinational company as the bogeyman of development—in determining scientific and technological research policies, not only in content but also in form.

Each of these observations must be seen in relation to a basic premise: that, in the words of a major study of the instruments of Latin American science and technology policy financed by Canada's International Development Research Centre, "the development of indigenous science and technology capabilities [is] an essential condition for achieving a certain degree of autonomy in decision-making on industrial development."

The experiences of both Venezuela and Peru in putting flesh on the bare bones of such statements have implications for other developing countries. Venezuela, for example, has attempted to develop a centralised strategy for its research policy through the creation of a National Council for Science and Technology (CONICIT), a model adopted by several other countries in the region. But the explicit goals of this strategy have been undermined by the consequences of an economic policy which, in pursuing rapid industrialisation, has encouraged joint ventures between foreign multinational companies and local capital. The result has frequently been to stimulate, rather than restrain, the flow of foreign technology into the country, providing companies with little incentive to support an indigenous research and development capacity.

Peru's problems have been slightly different. Since taking power in 1968, the country's military rulers have attempted to pursue a strongly independent economic policy; this has included not only the nationalisation of basic industries, but also the rapid increase in research budgets (up by a factor of 10 since the late 1960s) and support for both public and private research institutes. Subsequent moves to centralise science planning, however, seem destined to be moulded, at least in part, by the economic measures being demanded by the International Monetary Fund; these have been made the condition for bailing Peru out of the plight caused among other things by high military spending and the declining world price of copper.

In both Venezuela and Peru, science and technology policy is increasingly coming to reflect the domestic role played by foreign capital. And the danger of this is that it

skews decision-making to favour research and development policies, for example those concentrating on capital rather than labour-intensive production techniques, that benefit the upper and intermediate groups in society but have little impact on the plight of the poorest. Even where a "basic needs" technology is simultaneously advocated, this lies open to charges of "buying-off" the demands of the latter for an equitable share in the fruits of development.

Such issues can no longer be ignored by those concerned about the role of science in the development process. Fifteen years ago, the argument that the path to development lay in the rapid transfer of scientific and technological knowledge to the Third World, led participants in a United Nations conference to list priorities for such transfer in a "World Plan of Action". Today it is accepted that limitations and constraints on the transfer process are such that this philosophy is no longer adequate; indeed these limitations and constraints are the main focus of consideration.

This shift, embodied in the agenda for next year's United Nations Conference on Science and Technology for Development (UNCSTD), itself implies recognition that science and technology lie at the very heart of the development process. In practice, it is also coming to be recognised that policy matters in these areas can no longer be legitimately left to groups of experts, scientific or otherwise, but can only be forged through the type of bargaining and negotiation conventionally limited to more overtly political areas of national and international diplomacy.

Here there are lessons to be learnt from the recent UN conference on Technical Co-operation Among Developing Countries (TCDC) in Buenos Aires last month. Despite gloomy forebodings for the conference which predicted that the "real issues" would disappear in a storm of political acrimony, the meeting seems to have turned out relatively successful. In particular, the developing nations were able to unite behind a coherent and well-thought out position; and their combined strength was sufficient to add considerable bite to the draft plan of action which had been submitted by the UN secretariat, for example giving them greater control over the allocation of technical development funds.

TCDC marked an important shift from confrontation to negotiation that other UN conferences, including UNCSTD, would do well to try to follow. Certainly there are common scientific and technological interests between rich and poor nations; but given that these reflect broader social goals, no-one should be surprised that there are also conflicts. How to make such conflict productive, rather than merely self-defeating, is one of the most important issues that UNCSTD will have to confront. Encouraging joint research projects between developing countries, for example, can both provide practical benefits and increase the negotiating strength of the countries concerned; and ultimately it is this which determines who gets what share of the cake. □

DNA: let the public choose

Susan Wright, a historian of science at the University of Michigan, has followed the recombinant DNA debate closely. Here she comments on the recent public discussion of the revised NIH containment guidelines.

MUCH attention is currently being given to the concept of 'public participation' in policy decisions on technical and scientific matters. In referring to decisions on recombinant DNA research during a commencement address at the University of Michigan, Joseph Califano, Secretary of Health, Education, and Welfare, emphasised the importance of due process: "This means decisions made democratically through wide consultation, not by special elites". The tension in that statement, between "democratic" procedure and "consultation" (the results of which may still be digested by an elite group), points to a problem itself. Technical policy-making bodies are older than the growth of interest in participatory forms of decision making. They reflect an earlier faith in delegation of responsibility to high-ranking civil servants and expert advisors.

The political distance between current demands for participation in policy decisions on science and technology and the actual composition and procedures of policy-making bodies is nicely illustrated by the arrangements adopted by the NIH for decisions on recombinant DNA research. The elite nature of those arrangements was a principal subject of testimony at a hearing on proposed revisions to the NIH guidelines held at the Department of Health, Education, and Welfare in September before a committee chaired by Peter Libassi, HEW general counsel. NIH officials have claimed that all sectors have contributed to decisions on the guidelines through hearings and through the publication for comment of the guidelines, proposed revisions, and an environmental impact statement. However, testimony on the proposed revisions shows that many sectors see those procedures largely as a means for legitimising decisions taken within biomedical research circles rather than for facilitating participation in decisions.

The proposed revisions to the guidelines (10 August, page 411) are substantial: lowering of containment levels for many classes of experiment; exemptions which would take many experiments out of the guideline's control; and delegation of important responsibilities from NIH to local biohazards committees. Under the changes, local committees would be given wide responsibilities for recombinant DNA experiments. At a time when recombinant DNA technology promises to become as important for industry as it is for the universities, the revisions are a major step towards dismantling the central controls established two years ago.

All those who testified in support of the revisions were scientists and administrators with close ties to biomedical and agricultural research. Their reasons for approval were generally in line with those given by NIH director Fredrickson in his introduction to the guidelines. Delegation of authority to local biohazard committees was seen as a step in the right direction.

Critics of the proposed revisions included scientists and lawyers with ties to state and local government, trade unions, and public interest groups as well as to the universities. A concern expressed repeatedly at the hearing was that the circle of participation in decision-making has been largely restricted to a small group of scientists with close ties to NIH. According to Philip Bereano, a lawyer and professor in the University of Washington's Social Management of Technology Program, NIH decision making has

been dominated by an "old-boy network"—a reflection, ultimately, of the basic conflict of interest of the NIH in attempting to regulate an activity that it also promotes. Bereano's claim was supported by data from an NSF-funded study of the composition of institutional biohazard committees (IBCs) reported by Nancy Pfund of Stanford University. Preliminary results show that the proportions of workers, students, and members without ties to the institutions doing the research averaged less than 2% and that almost 70% of the membership was drawn from scientists and administrators in such fields as microbiology, biochemistry and molecular genetics.

Witnesses noted that growing industrial interest in recombinant DNA means that the NIH advisory committee will be called on increasingly in the future to make policy recommendations with far-reaching social implications. Fredrickson's proposal to "broaden [the committee] modestly as needed for expertise" and "to include, perhaps, a dissenter from NIH policies" was seen as an inadequate response to those demands. In written and oral testimony, representatives of the Attorney General of New York State, the American Federation of Labor and Congress of Industrial Organisations, the Coalition for Responsible Genetic Research, the Environmental Defense Fund, and Friends of the Earth called for substantial expansion of the committee to include members of trade unions, public interest groups, public health organisations, and government agencies with potential regulatory jurisdiction. In addition, Friends of the Earth lawyer Richard Hartzman stated that the proposed changes were so sweeping that they required a new environmental impact statement.

The proposal to delegate responsibility for oversight to local institutions also received strong criticism. Pointing to violations of the guidelines that have occurred at Harvard Medical School and the University of California, San Francisco, commentators suggested that to respond to those events by enhancing rather than by checking responsibilities of local committees was inappropriate. "NIH proposes a form of enforcement which institutionalises conflict of interest and provides even less accountability for the Director of NIH and the IBCs than the previous guidelines," wrote Marcia Cleveland and Louis Slesin of the Natural Resources Defense Council. This matter is also of concern to Assistant Secretary of Labor Eula Bingham and Senator Adlai Stevenson, chairman of the Senate subcommittee on Science, Technology, and Space, both of whom have proposed retention of more centralised controls.

Critics have also claimed that the closed form of decision-making had affected the quality of the technical evidence used in reaching decisions. "There has been heavy reliance on unrefereed, unexamined reports of small committees meeting in private which are then presented as the consensus of the scientific community," said Jonathan King, associate professor of biology at MIT. He stated that the results from those meetings had been used in an "extraordinarily selective manner in which no arguments that countered or failed to support claims were either quoted or referred to."

How will the DHEW handle testimony on the revisions? Will a full environmental impact statement be necessary? Libassi after the hearing declined to say what he would do, but, echoing Califano's words, he did say that he thought the issues raised were "not ones to be decided by scientists." As to his own role: "A lawyer's skills can be applied in technical areas as well as procedural ones." Clearly, several government sectors and the public will follow closely how the sentiments of Libassi and Califano are translated in terms of expansion of the present circle of recombinant DNA decision-making □

Where should LEP be built?

Europe's bid for a world lead in subnuclear physics in the 1990s brings CERN's future into question, writes **Robert Walgate**

EUROPEAN subnuclear physicists are brimming with enthusiasm for their next big project, LEP (see page 482), but building it will plunge CERN (the European organisation for nuclear research) into a hornet's nest of problems.

There is strong competition—tacit or not—between CERN and the West German laboratory DESY for the siting of LEP, a large electron-positron storage ring; and there is controversy over CERN costs, with large tax-free wages accounting for over half CERN's expenditure. The French, German, and British governments are insisting that the CERN budget be brought down from its present 600 million Swiss Francs (MSF) a year to 560 MSF by 1981, but LEP can only be built at reasonable speed (in under a decade) if CERN has some 600 MSF a year.

Meanwhile, the tacit international understanding that the next machines would be continental, with the USSR building a 3 TeV proton synchrotron, Europe building a 100 GeV electron-positron storage ring (LEP), and the US building Isabelle (a 400 GeV proton storage ring), has been violated with the news that the US is also looking at a LEP-like project. Burton Richter, the Nobel laureate who led the discovery of charm with LEP's progenitor, SPEAR, is reputed to be pressing the US government for an American LEP. And as the US Department of Energy is discussing collaboration with Japan on a number of research issues, including subnuclear physics, it is conceivable that Professor Richter will find Japanese money to build a LEP ahead of Europe despite US expenditure on Isabelle and Fermilab. The race is on, and as one CERN physicist put it "the first to the money will get LEP".

The future of LEP in Europe is confused by a number of factors, one of which is the rising eminence of the German laboratory DESY. "Four years ago we were nowhere", a DESY physicist told *Nature*. "Now we are on top, and physicists are clamouring to work here". The root cause is the realisation that electrons, particularly in collision with positrons, are the cleanest probes of the nature of matter on small scales. DESY is Europe's largest electron laboratory. Further, DESY has succeeded in building PETRA.

PETRA is the world's largest storage ring for electrons and positrons, with (at 19 GeV) twice the energy per beam of SPEAR (and its equivalent at DESY, DORIS). It will begin experiments on

22 October, eight months ahead of schedule, though it may take a month or two before its intensity reaches design levels. It will probe new quark combinations (like 'bottomonium') and most likely reveal new quarks ('top' is expected) and leptons. And with an experiment devised by Samuel Ting (co-winner with Burton Richter of the Nobel Prize for the discovery of the 'hidden charm' particle J/psi) it will test the unification of the weak and electromagnetic forces proposed by Abdus Salam and Steven Weinberg. PETRA will give European subnuclear physics a world lead for five years or more.

Experience in building and running PETRA also gives DESY physicists a European lead in the design considerations for LEP. But there was not a single DESY representative on the 63-man CERN study of LEP, recently completed (CERN/ISR-LEP/78-17, the 'Blue book'). Professor Schopper, the director of DESY, argues that the best contribution that DESY could have made was to build PETRA, rather than to work on "a paper study"; and anyway the CERN team spent a long time at DESY, discussing the PETRA design. Schopper points out that several of the design points in the CERN study are a simple scaling-up of PETRA elements—the rf cavities, for example, and the vacuum tube. DESY physicists were of course spending 16 hours a day building PETRA, but the DESY absence from the study has also been interpreted as a political manoeuvre; so much so that the brief presence of several senior representatives of DESY, including the builder of PETRA, Gustav Voss, at the CERN summer study on LEP recently was seen as something of a thaw.

All this would matter little if it did not involve the future of CERN. The CERN budget is under pressure from its staff (some 4,000 people, mostly technicians) whose promotions have fallen to a low ebb, and who are, of course, keen to maintain salaries at their high level. (50% of the staff live in France, where they could earn only half the sums they cull from CERN; a study, called RESCO, is underway on the social conditions and remuneration of workers at CERN.) The budget is also under pressure from the Swiss Franc, in which CERN subscriptions and salaries are payable. The franc has strengthened from 12 SF to the £ in 1966 to 3 SF at present, quadrupling the British subscription over that

Who should CERN fear most: Chancellor Schmidt (left) or DESY director Herwig Schopper?

period. And the budget is under pressure from the other direction from the member states, who want to keep their expenditure on subnuclear physics in proportion to their other research costs. The CERN-built LEP would cost some 1000 MSF, but as a French physicist commented, "what will that mean in 10 years in pounds, or French francs, or even Deutsche marks?"

According to one influential physicist, the European Committee for Future Accelerators (ECFA), which has been charged by CERN members with producing a firm proposal for LEP, has in its hands a very delicate decision. The committee, he said, has to consider which course of action for LEP would preserve the best future for subnuclear physics in Europe. LEP at CERN's Geneva site might price itself out of the market. And CERN without LEP in the 1990s would be a dying laboratory. The question seems to be whether the focus for subnuclear physics in Europe should move for the 1990s from Geneva to Germany (though there are other contenders, notably France; only Italy has ruled itself out).

CERN defends itself strongly, pointing out that a new laboratory would need a new infrastructure, entailing extra cost; that LEP at Geneva would allow collisions between the electrons of LEP and the protons of the SPS, allowing an ultradeep probe of proton—and perhaps quark—structure; and

that the LEP tunnel, once built, could be used for many other purposes at CERN, with its complex of accelerators

Over at DESY, Professor Schopper is at pains to protest that there is no competition between his laboratory and CERN; but other DESY physicists see it differently. "We are planning moves like a chess game", said one. And DESY can afford to sit tight for the moment: it is in a strong position, technically and politically. On the technical side, pressure from physicists for the highest possible energy favours DESY. High energy means large ring size to reduce the synchrotron radiation losses from the circulating electrons (and so keep down the power bill). But the CERN site is restricted by the Jura mountains to the north. DESY's presently favoured site, in a national park 40 km south of DESY near Hamburg, is not so restricted.

However, an early CERN study of a 100 GeV machine (LEP-100) was abandoned. The 'Blue book' argues that there will be many difficulties in handling electron beams at 100 GeV. The summer study concluded that "improving the energy [beyond 70 GeV] requires far more knowledge of a theoretical and technical nature before a realistic design may be settled upon"; but Schopper says that such conclusions are premature, and based on a too-pessimistic interpretation of work on the problem at DESY. In principle DESY should know, but it is not easy to disentangle physics from politics on this point.

The present half-cost LEP planned by CERN is a project for 70 GeV beams (LEP-70), with a possibility to upgrade to 100 GeV if superconducting rf power cavities become feasible. One of the key tasks for LEP will be to produce the intermediate vector bosons, which have masses and properties such that the neutral Z^0 could be produced with single beam energies of about 45 GeV, while the charged W^+ and W^- would need 80 GeV. The Higgs bosons, which are essential to the unification of the forces, and hold the key to the masses of the quarks and leptons, require the highest possible energy. LEP-70 is not therefore the most comfortable machine for physicists—100 GeV would be better—although there will be a cornucopia of treasures on LEP-70 from the "resonance" in the interaction at the Z^0 , which should yield a thousand-fold increase in interaction rate.

ECFA is just beginning studies of the machine parameters for LEP, under the chairmanship of Professor Antonino Zichichi—who intends to be entirely "Galilean" in his considerations. In other words he wants his committee to come up with the physi-

cists' perfect proposal, without regard to politics. That study is due at the end of 1979 for presentation to ECFA and to CERN Council. It will be interesting to see whether it more nearly approaches LEP-70 or LEP-100. ECFA will then have to juggle with site and politics to come to its recommendation.

John Adams, CERN's machine-building director-general, said in Geneva recently that he would like physicists to reach agreement on a site "by the end of next year". He added "If the physicists can't decide where to put the thing they can't blame governments for delays". And there are further battles to be won at government level.

Germany lost the fusion project, JET, to the UK, and might welcome a new international laboratory. Professor Schopper insists that any extension of

Argentina— where thought is a crime

DR CLAUDIO BERMAN, a professor of psychiatry held incommunicado in Cordoba prison in Argentina without specific charges since April 1976, was released last month, following pressure from the US National Academy of Sciences' Committee on Human Rights, the Israeli embassy in Buenos Aires, and international human rights groups.

Dr Bermann was released into the custody of an Israeli representative only when he was actually aboard the aircraft bound for Israel. On arrival in Israel, he avoided any formal contact with the Press, apparently fearing for the safety of fellow-prisoners still in custody. It was, however, possible to learn informally some interesting sidelights on the position of psychiatrists in Argentina, and, in particular, the reason why so many psychiatrists figure in the lists of political prisoners and 'disappeared persons'.

"Thought is a crime there," explained a friend of Dr Bermann's cynically. More particularly, psychiatry which, as a therapeutic discipline, aims at establishing the autonomy of the individual, is seen by the present regime as potentially subversive—an opinion which draws some substantiation from the fact that, until 1973, the Argentinian Federation of Psychologists did, as a matter of fact, have a large number of members whose political leanings were leftist or liberal. Freudian psychology is banned from the universities (where it is seen as a Marxist subversion unlike the Soviet Union where it is condemned for being anti-Marxist!), and, according to

DESY would be "fully international", with contributions from no country ruled out (including Japan). And the small countries at CERN will not be happy with the closure of CERN's low energy synchrocyclotron and the intersecting storage rings, as will be necessary if CERN is to build LEP within its 600 MSF ceiling. The Scandinavian countries, in particular, make good use of the synchrocyclotron for nuclear physics, and the intersecting storage rings are now ready for nuclear physics experiments with light nuclei.

CERN's problems with LEP are manifold, and it is no wonder that before John Adams gave his recent talk at CERN on "steering LEP" to an enthusiastic audience of physicists his colleagues told him, "And for God's sake be cheerful"

Robert Walgate

"I keep thinking I'm two psychiatrists"

another expatriate psychologist, university teaching in psychology goes no further than the writings of St Augustine and St Thomas Aquinas.

Furthermore, said the same psychologist, difficulties can arise in the therapeutic situation. A psychiatrist might attempt to treat a patient's anxieties by presenting the current regime as an unpleasant, unavoidable fact of life, which one must somehow learn to live with. Further there are reports of members of guerilla groups actually receiving treatment from psychiatrists without the psychiatrist actually knowing anything about this side of their activities—a proposition which seems at first glance somewhat unlikely, but which, within a group therapy context, is quite feasible.

Acting on suspicion of some such link between psychiatrists and guerillas, the Argentinian authorities have, according to Dr Bermann and his friends, been putting pressure on practising psychiatrists to betray their professional confidentiality, and, in some cases, it would appear that agent-

provocateurs have been used, posing as guerrillas in need of treatment, to determine the "loyalty" of the psychiatrists.

According to Dr Bermann, when first arrested, he was himself tortured in an attempt to establish a link between him and the guerrillas. When the authorities finally realised that he had no information to give them, he was put in a cell with other "political prisoners who knew nothing," from which the sounds of others being tortured could be heard.

Dr Bermann, as a professor and former director of a psychiatric clinic, ranked as an important prisoner—and as such was chosen as a kind of hostage when President General Jorge H. Videla visited Cordoba last year. Twenty such hostages were arrested—though as incommunicado prisoners they could do nothing to avert any possible attack on the presidential party. Nevertheless, their fate depended on the safety of the President and his entourage, according to an equation

which seems to be a peculiarly Argentinian way of assessing the value of its leading citizens.

If there was any attempt on the President's life, they were told, all 20 would be shot; if a General was killed, 14 would be shot, if a colonel, eight, and if any other official or policeman were killed, only two. So, by the new Argentinian mathematics, it would appear that one leading psychiatrist equals half a policeman!

Vera Rich

US producers fear ban on 2,4,5-trichlorophenol

SOME of the producers of 2,4,5-trichlorophenol fear that it might be banned in the US. The Environmental Protection Agency (EPA) has recently issued a notice of 'rebuttal presumption' against current and continued registration of trichlorophenol and its salts. The notice—the first of several which the agency intends to issue—says that they exceed "certain risk criteria".

The issuing of a rebuttal presumption is not, says the agency, notice of intent to ban the products. Such action would only be taken after careful evaluation of all the evidence had shown that their continued use would cause "unreasonable adverse effects to the environment". However, the notice does require that the users and manufacturers of trichlorophenol submit evidence to the EPA, proving that its continued use does not constitute a hazard.

This is not the first time that the EPA has reviewed these particular chemicals. 2,4,5-trichlorophenol is used in the manufacture of the herbicide 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) and of the bactericide, hexachlorophene. The reaction process used to make trichlorophenol produces an extremely toxic by-product, tetrachlorodibenzo-p-dioxin (TCDD). It is the presence of TCDD—a known teratogen and potential carcinogen—which is causing the current concern.

2,4,5-T has been reviewed recently by government committees in the UK and Australia, both review bodies pronounced the herbicide safe if used for the purposes for which it is intended. Manufacturers are less optimistic about its chances in the US.

Among the most recent evidence that the EPA will examine are two sets of documents relating to the safety of the manufacturing process. The first is the Italian Parliamentary Commission's

report of its investigation into the accident which occurred in the ICMESA trichlorophenol reactor near the Italian town of Séveso nearly two years ago. The second is the report of ICMESA's Swiss owners, Givaudan and Hoffman-La Roche, on their own research into the cause of the accident.

Their report is in reply to the commission, but it has been prepared especially for the EPA. The commission's report, which runs to several hundred pages, accuses Roche and Givaudan of being less than candid about their operations at ICMESA and of running an unsafe chemical plant. The commission also claims that ICMESA was producing trichlorophenol without an up-to-date 'fire precautions certificate'; that it failed to inform the Labour Inspectorate that it had begun production of trichlorophenol, that it failed to notify the authorities of the accident for twenty-seven hours; and that when it did inform them, no mention was made of the release of TCDD.

ICMESA produced 130 tons of trichlorophenol in 1975 and 1976; a sizeable amount, according to the Italian commission. Roche and Givaudan will contend in their report that compared to the output of companies in the US and Germany this is a small amount. The commission's suggestion that the trichlorophenol reactor was poorly designed, is refuted by Givaudan, who claim that their design incorporated all the features necessary at the time for safe reactor operation.

The ICMESA reactor did not incorporate a dump tank to collect unwanted discharges from the reactor vessel. Givaudan thought this unnecessary, in view of the plant's other safety features. The commission, however, thinks this was a serious error,

A safety disc on the vessel was designed to rupture at the pre-set pressure of 3.5 atmospheres, and so discharge TCDD over Séveso. The Italian report states that a lower value would have caused a rupture at a less advanced stage of the reaction, with less disastrous consequences. Givaudan argue that the disc was incorporated to cope with mishaps at the beginning of the trichlorophenol reaction process—the accident at Séveso happened some six hours after the reaction was completed—and that the rupture pressure of the disc was selected for sound chemical reasons.

Central to the concern about the health of Séveso's inhabitants is the two week delay in their evacuation from TCDD contaminated areas. The commission says that Roche and Givaudan did not act swiftly enough to determine the extent of contamination. The companies contend that after a map of the polluted area had been made—a task which took two weeks—the proper authorities were informed and recommended by Roche to evacuate the area. Roche says that the authorities resisted initially until they appreciated the gravity of the situation.

Many scientists think the Séveso residents were exposed to low levels of TCDD. The commission disagrees, and recommends further studies to assess the long-term effects to health. TCDD is a potential carcinogen, and numerous scientists consider such studies essential. The International Agency for Research on Cancer (IARC), which has recently published a new report on the polychlorinated dibenzodioxins is currently assessing the chemicals' carcinogenicity. It is reviewing evidence from a number of the fourteen accidents which have occurred in trichlorophenol plants since 1949.

Alastair Hay

Venezuela: still out in the cold

If Latin American research centres were graded by location, the greatest number of stars would surely be awarded to the Venezuelan Institute for Scientific Investigation (IVIC). Set on a mountain-top retreat 20 miles outside Caracas, its lush forest surroundings complemented by imposing works of modern sculpture, IVIC has all the environmental requirements of the archetypal ivory tower.

Yet its very isolation reflects a major complaint of Venezuelan scientists. Despite concerted efforts over a period of years to link scientific research to the country's technological needs, their activities remain marginal to the country's main economic and industrial activities.

IVIC itself, through a combination of generous private and public funding, has become, since its foundation in 1959, one of the leading basic research centres in Latin America. Its facilities in fields such as biophysics and analytical chemistry attract scientists from all over the continent. They often rival those in the laboratories of industrialised countries in which many of IVIC's research workers received their initial training.

The institute has also been actively developing its own postgraduate courses. There is a proposal before the next meeting of the United Nations Educational, Scientific and Cultural Organisation (UNESCO) in Paris, for example, that IVIC should become an information centre for postgraduate studies for the whole Latin American region.

Despite its scientific successes, however, the institute and its activities remain highly vulnerable to the effects of the country's changing fortunes, according to its director, Dr Luis M.

Carbonell. Earlier this year, for example, a 7% across-the-board cut in public expenditure—a response to a growing balance of payments problem and escalating inflation—resulted among other things in a six-month moratorium on travel to international conferences.

IVIC's vulnerability is itself a reflection of the extent to which research in Venezuela remains marginal to the country's main technological activities. A policy of pursuing rapid industrialisation while oil revenues continue to come in has largely been carried out through the transfer of technology from abroad; and although research and development expenditure, judged on a per capita basis, is among the highest in Latin America, it is still only 0.28% of the gross national product, less than a tenth of the proportion spent by many of the industrialised nations.

An attempt to rationalise the country's scientific efforts and link them more directly with its technological needs was made ten years ago with the setting up as an offspring of IVIC the National Council for Scientific and Technological Investigation (CONICIT), one of a number of similar planning institutions which have been established in various countries in Latin America.

"The marginality of science in Venezuela has largely been the result of a lack of communication between the scientific and the productive systems. Since its creation, CONICIT has been taking action to confront this situation," according to the council's president Dr Pedro Obregon, a widely-respected plant geneticist.

One area in which the council has enjoyed considerable success has been

in increasing the skills of those responsible for purchasing foreign technology in choosing that which is most appropriate to the country's needs; centres have already been established in London and Vienna to assist in this purpose and another will shortly be opened in Washington.

CONICIT has also been successful in stimulating new research initiatives in fields such as health and agriculture. In the latter case, for example, it recently opened a Centre for Agricultural Technology. Yet despite concerted attempts, CONICIT has so far had little success in generating the interests from the direction that, at least as far as the country's economy is concerned, matters most, namely sectors such as the chemical and steel industry.

Such industries, often under the government's rapid industrialisation policy and its support of joint ventures between national and foreign capital, have preferred to import technologies from abroad, rather than building up an indigenous research and development infrastructure. "The problem has been getting local industry interested in local technology" as one observer puts it; and the result is that CONICIT has been relatively unsuccessful in achieving one of its prime goals, namely increasing the country's technological

Institute for Scientific Investigation: five-star location but vulnerable to budget cuts and inflation, says director Luis Carbonell (above)

independence from foreign interests.

"Apart from opening the minds of many people to the problem of relating science to technical needs, and providing funds for training, I don't think CONICIT has been able to do much more in achieving its original goals," says Dr Carbonell of, IVIC who points out that 95% of patents taken out in Venezuela are still foreign, and that of the remaining nationally-owned patents, hardly any have been exploited.

CONICIT's problems are reflected at IVIC itself. One of the effects of the marginalisation of science is, it is claimed, a lack of respect for basic science as a profession; salaries are considerably lower than in universities, where teaching loads are so heavy that relatively little research is carried out.

In recent years IVIC has, for both ideological and financial reasons, been attempting to shift its focus away from a primary concern for basic science to embrace more applied subjects as well. The institute now has a small but active programme in solar energy research, concentrating in particular on methods of growing cadmium crystals, and is planning an investigation into techniques for the gasification of coal.

The institute also has a small research reactor, used not only for train-

ing engineers in handling nuclear materials but also for producing isotopes for medical and industrial use. At present, Venezuela has no plans for a nuclear energy programme; "but we are training people to make the right decisions, when these become necessary," says Dr Carbonell.

So far, however, as with CONICIT, industry's response to IVIC's efforts in the field of applied science has been disappointing. "Although lip service is given to the need to develop applied research, there does not really seem to be much real demand for it," according to Dr Marcel Roche, IVIC's first director and now editor of the Latin American journal *Interciencia*.

"Venezuelan industry tends to go for the maximum benefits with the lowest risks. The result is that research remains peripheral to the interests of industry; and this is a situation which has not been changed by CONICIT."

One attempt to improve things has been the drafting of a new law, similar to that which was introduced in Peru in 1971 (see below), which would oblige all industrial enterprises, to contribute a proportion of their gross profits to a research and development fund administered by CONICIT.

"In the future, it is essential that

research receives financial backing from the industrial sector. Not only will this provide research institutions with more resources, but it will also help protect industry from foreign interests," says Dr Obregon.

If the proposed law is accepted by the Venezuelan Congress—and this will depend largely on the outcome of the forthcoming presidential elections, as well as new Parliamentary elections next year—the result will be to put CONICIT in a much stronger position not merely to plan, but also to carry out a coordinated research strategy. It could also increase its budget, currently less than \$2m a year, by a factor of up to ten.

And what about the future of basic science? Dr Roche, a firm supporter of the need for developing countries to build a basic research capability to encourage technological independence, is optimistic.

"In my lifetime I have had the opportunity to see Venezuelan science grow at a relatively impressive rate. When I began to do research, there were in the country only six or seven professional investigators; now there are hundreds, well prepared and competent." □

Peru rings the changes in science policy

PERU has become the setting for a fierce debate on the respective roles that scientists and government planners should play in the design and administration of a national science policy. The focus of the debate is a proposal now before Peru's military leaders to upgrade the country's National Research Council, at present a primarily advisory body made up of eminent scientists, and to use it as the basis for establishing a "national system for science and technology"

The proposal is being resisted by groups such as the Institute for the Research in Industrial Technology (ITINTEC), which claim that a strongly centralised research policy would restrict the advantages of flexibility gained from the present system of relatively autonomous research institutes, each linked to separate government departments.

Others, including members of Peru's National Planning Institute—a government agency whose director has ministerial status—while agreeing on the need for a central programme for science and technology, argue that it should be conceived within, rather than parallel to, the existing social and economic planning machinery.

The root of the current conflict can be traced back to an ambiguity that

has existed since Peru's military government came to power in 1968. Keen to restrict the power of foreign interests and promote the country's technological independence, the government has encouraged the growth of a network of sectoral research institutes. There are now about 230 separate research institutes in Peru, half in the private and half in the public sector. And many, such as the Instituto del Mar del Peru (IMARPE) in Callao, enjoy an international reputation. At the same time, however, the government created as one of its first post-revolutionary acts the National Research Council, which theoretically has responsibility for establishing a national science and research policy.

"The problem is that when the government set up the council, it did not provide it with the authority or the resources to carry out the responsibilities it had been given," according to the council's current president, Dr Antonia Pinilla. "In consequence, the council has not been able to play the leadership role that it should have done."

As a remedy, Dr Pinilla, a previous Minister of Labour and a co-founder of the private University of Lima, has proposed a "national system" for coordinating the country's research

efforts (Such a system has already been promised by the government in its Tupac Amaru Plan for returning to civilian rule by 1980)

The system would have two main components. The first would be a National Council for Science and Technology, a "normative body" responsible for setting policy goals and research priorities. The council would be made up of eminent scientists and those responsible for the various scientific and technological research institutes. The second would be an administrative body known as the National Institute for Science and Technology. In addition to carrying out the policies determined by the council, the institute would be responsible for setting up both an Advanced Centre for Science and Technology—a type of "Peruvian MIT", as Dr Pinilla describes it, concerned with postgraduate studies and research—and a national Centre for Scientific and Technological Documentation.

Dr Pinilla has suggested that the head of the national system act as both president of the council and as director of the institute, and that in recognition of the central role of science and technology in the country's economy, he or she be given equivalent ministerial status to the director of the

National Planning Institute.

The proposed science policy machinery has received enthusiastic support from amongst others, the science policy secretariat of the United Nations Educational, Scientific and Cultural Organisation (UNESCO), which has been promoting the "minister of science" approach for a number of years.

Others inside the country, however, are less enthusiastic. Despite Dr Pinilla's promise that the system will "respect the academic autonomy" of individual research institutions, they are worried that attempts will be made to impose unrealistic goals and objectives while limiting flexibility.

Particularly concerned are members of ITINTEC, an agency set up by the government in 1971 to stimulate research in the various areas of productive industry. At present, although working to support areas that have been given priority by the government, ITINTEC is able to operate relatively independently because its main income comes directly from industry.

Under the law establishing ITINTEC, all companies in Peru have to set aside 2% of their gross profits each year for research. A company can either submit for ITINTEC's approval a research project which it wishes to carry out itself, or hand the money over directly to ITINTEC, which will use it to finance its own research.

The model seems to have worked quite well, and the Venezuelan government is contemplating introducing a similar system (see above). Over a third of ITINTEC's research projects are carried out by universities, and the institute has established centres for wood technology and non-metallic materials, as well as what is claimed to be the best technical information service in Peru.

Furthermore ITINTEC has recently received a \$2 million grant from the US Agency for International Development to investigate the application of "appropriate technology" ideas to Peru—a project which will include studying the possibility of restoring the famous agricultural terraces built by the Incas, now realised to be a highly efficient means of using soil and rain-fall in mountain areas.

Under the proposed new system, although ITINTEC and other research institutes would remain responsible for developing and carrying out their own research programmes, they would be required to present plans and budgets to the National Council for prior approval. "We feel strongly that technological research and development should be carried out within each sector of industry, without being subject to any strong centralised control, which we have been lucky enough to avoid in the past," according to Dr

Inca terracing: old but efficient

Jorge Boggio, ITINTEC's director of technology. "Also, although we agree on the need to coordinate the country's scientific and technological research activities, I think it is wrong to give responsibility to a body whose members have had little experience of technological development.

Related views are expressed at the National Planning Institute, which has had a strong influence on carving out Peru's highly nationalistic industrial policy in recent years. "I feel that our country needs a very clear and long-term plan for science and technology, but it must be built on the long-term objectives of socio-economic planning," says the director of the institute's office of research and planning, Dr Fernando Gonzales Vigil. "We need to determine broad priorities first, and then inside these priorities to put an emphasis on specific areas of knowledge, rather than the other way round."

Much will depend on the attitude of the new Minister for Industry, Admiral Jorge Du Bois Gervase, a former head of the industrial service of Peru's navy and therefore, it is claimed, well aware of the problems of relating research to operational needs.

Another factor will be the effects of the austerity measures that the government has been forced to take to avoid defaulting on its loans from the International Monetary Fund. Although a proposal to eliminate industry's required contribution to ITINTEC has been successfully headed off, for example, the institute remains vulnerable.

But whatever the outcome, many feel that the policy finally adopted is likely to be one that increases support for the private sector, and weakens the role of state planners. "This would be the more logical outcome, taking into account the various national and foreign interests," says Dr Vigil. □

Andean Pact propose research tax on 1st world

ALREADY bidding for a place on the agenda of next year's UNCSTD meeting in Vienna is a proposal that has been put forward jointly by a group of Latin American countries and the Economic Commission for Latin America (ECLA) to establish a new fund for supporting technological development ventures in the Third World.

The countries concerned—Bolivia, Colombia, Ecuador, Peru and Venezuela—are members of the Andean Pact, an economic federation formed in 1969 to harmonise and coordinate the economic and technological policies of its constituent states.

From the beginning, the Andean Pact countries have expressed, mainly through the reports and studies of its secretariat's technical group, the Junta del Acuerdo de Cartagena, fierce criticism of the way that existing technology transfer and patent licensing policies have increased the dependency of the developing on the developed world.

The proposed fund is intended to strengthen the indigenous research and development capacities of developing countries. Contributions would be based on the size of the balance of trade on manufactured goods between rich and poor countries, with the general assumption that the greater the imbalance, the greater will be the technological gap.

Details of the proposals are now being revised in the light of comments made when the idea was discussed at the UNCSTD regional meeting for Latin America in Panama in August. Although doubts were raised by some of the countries present—mostly those claiming to be at an "intermediate" stage of development—others gave it enthusiastic support.

The Pact's position on technology, spelt out in a joint Decision 84 signed in June 1974, is based on the premise that if a country is to have control of its own development programmes, it is not enough merely to control the investment of capital (for example by regulating the financial activities of multinational companies). Equally important is control over the development and use of technology.

"It is easy to show, for example by looking at the way that the patent system has been used, that unless you have people who can control the

Cooperation to improve production technique. Left: coppermine in Chile. Right: ore analysis in Bolivia.

technology—and not just capital alone—you will remain in a position of dependence on the industrialised nations,” says Dr Luis Soto-Krebs, a Chilean metallurgist who is director of the Junta’s science and technology policy group.

One paragraph of Decision 84 states that “the high fixed costs of research and development necessitate careful choice of research priorities and the avoidance of duplication of effort”. The member countries agreed to develop sub-regional methods for generating new technologies through the application of local knowledge and research, and also to apply these techniques to some pilot projects.

One of the first projects was to improve techniques for copper production, a major source of revenue for Peru, Bolivia, and Chile (which was until 1975 a member of the Andean Pact).

Two problems were tackled simultaneously. The first was to develop new hydrometallurgical techniques for extracting copper from low grade ores; the second was to build up, virtually from scratch in the case of Bolivia, indigenous research and development that would cut down dependence on foreign technology and know-how.

Engineers and scientists from Peru and Bolivia went to Chile—the most advanced of the three in copper technology—for a one-month seminar in 1974 on the theory and laboratory-practice of copper extraction. They also spent some time working in different types of extraction plants in Chile. “The basic idea was that everyone in the project should have a common language; that people in the lab should know about the problems of the plant, and vice versa,” said Dr Soto-Krebs.

Members of the Bolivian team, which concentrated on methods of using conventional sulphuric acid leaching of the oxide ores, set to work on the design of a plant planned for the Corocora area by the Bolivian Mining Corporation (COMIBOL) that would process between 300 and 600 tons of ore a day.

Much of the work involved basic geological studies of the site of the

plant, and of the properties of the ores—often using testing facilities made available by Peru. Three years’ work resulted in detailed plans for what is proudly called “the first Bolivian-designed copper extraction plant” being handed over at the Junta’s headquarters in Lima earlier this year.

Officials hope that capital for building the plant will soon be made available, probably by West Germany, which helped to subsidise the initial research and development work. They also point out that the team which drew up the plans now has the experience to tackle other similar projects.

The Peruvians carried out much of their project in a research laboratory set up in La Oroya, the centre of Peru’s mining industry. The aim was to investigate ways of exploiting bacteriological leaching techniques for concentrating the ore, already known about by larger copper companies in the US, but little used or understood.

With the help of a German scientist who had been studying the relationship between bacteria and crystal structures, and two Canadian scientists who had been looking at applications of bacteriological leaching, Peruvian biochemists were able to separate out and reproduce those bacteria most suitable to local ores. Starting from ore samples no larger than 300 grams, the research built up until it was able to build and operate a pilot plant. “It soon became clear that we were almost in the front line of this research, and we came out with a method for very fast leaching very different from what was already being done,” says Dr Soto-Krebs.

The pilot plant is now producing two tons of copper a day at a considerably lower cost than conventional extraction techniques. Bacterial leaching also has the advantage of being non-polluting—since there are no exhaust gases to discharge into the air—and of being applicable to much lower grade ores than could previously be handled.

Since the success of the two copper projects, two other technological development projects have been set up by the Junta along similar cooperative

lines, one studying the use of forest products, a second looking at nutrition and food production. Other projects in the pipeline include a proposal for a joint investigation of techniques for the gasification of coal, of which Venezuela and Colombia in particular have large deposits.

“Too often our people are convinced they can do nothing . . . but we have now convinced people at the highest level that carrying out our own technological development is not a dream, and that investing in the generation of such technology is not useless,” says Dr Soto-Krebs.

Financing for similar types of projects could, it is claimed, be provided by the new fund which is being suggested to UNCSTD. The idea for such a fund was first raised at a meeting in Caracas earlier this year by Dr Francisco Sagasti, the Peruvian co-ordinator of a five-year study of science and technology policy in Latin America that has been financed by Canada’s IRDC.

“One area of top priority in stimulating cooperative research ventures between developing countries is providing financial support,” says Dr Sagasti. “What is being suggested is that the developed countries make available a sum proportional to the imbalance in trade in manufactured goods with the developing nations, calculated on a regional basis.”

Dr Sagasti estimates that, using 1977 trade figures and calculating on the basis of 0.25 per cent of the trade imbalance in manufactured goods, Latin American countries would receive about 60 million from the USA, Japan and members of the EEC alone.

“Such a mechanism would help to increase significantly the flow of funds for scientific and technological activities in the Third World, thus initiating a gradual process of redistribution of the world science and technological effort,” said Dr Sagasti. □

Fusion first for USSR

SIR,—A short report was published (*Nature* 269, 370; 1977) concerning the "generation of neutrons by thermonuclear fusion using a concentric explosion with an exceptionally high degree of symmetry". The results were obtained by the Polish group headed by Professor S. Kaliski and were announced at an international conference in Prague.

Similar results obtained in the Soviet Union were made public in 1958 by L. A. Artsymovich at the Second International Conference of the Peaceful Uses of Atomic Energy held in Geneva. (L. A. Artsymovich, *Controlled fusion research in the USSR; Proceedings of the Second United Nations International Conference of the Peaceful Uses of Atomic Energy*, 2298, 31, 1958).

As early as 1955, 10^8 neutrons per impulse were generated in our experiments (which were mentioned by L. A. Artsymovich) by focusing converging spherical shock waves on a UD_2T target. In 1963 for UD_3 and gaseous D_2 targets this number was increased to 3×10^{11} . The converging shock wave was formed by implosion of a spherical charge of explosive. In most of the experiments the external diameter of the design was about 70 cm, the mass of gaseous D_2 being about 3×10^{-4} g.

Correspondence and papers of Michael Polanyi

SIR,—A major part of Michael Polanyi's papers is now in the Joseph Regenstein Library at the University of Chicago. These are the papers that were in his possession in Oxford, but no systematic effort has been made so far to collect correspondence, manuscripts and memorabilia from people with whom he was in touch. The question as to how to collect this material comes at a time when a biography is being undertaken by Professor W. T. Scott of the University of Nevada in Reno. In the effort to combine the advantages of having original documents available for scholarly use at a centre in Britain, with access to the material by the biographer, and ultimate deposit of copies in the Chicago archive, we wish to make the following request.

We ask anyone possessing such material to make copies, and to send the originals to Miss Cicely Argyle, 12 Sunderland Avenue, Oxford. She will acknowledge receipt, and will deliver the material to the Contemporary Scientific Archives Centre in Oxford. This centre, under the direction of Professor Margaret Gowing, will process and catalogue the material and deliver it for permanent deposit to the Bodleian Library.

The making of copies before entrusting documents to the post is clearly important.

The biographer would appreciate having these copies sent to him, and undertakes to see that when he has made use of them they will finally be sent to the archive in Chicago to fill out that collection. He would also appreciate receiving any recollections and memorabilia, as well as suggestions of other sources of material. His address is: Professor W. T. Scott, Dept. of Physics, University of Nevada, Reno, Nevada 89557 U.S.A.

Effective trypanocides

SIR,—I was astonished to read the statement by your contributor Hugo Van den Bossche in his article 'Chemotherapy of parasitic infections', (22 June, page 626) that Berenil "is at present the only effective trypanocide left for use in cattle".

The reference given for this information is 'Williamson J., *Trop. Dis. Bull.* 73, 531-542 (1976)'. It is most unfortunate that an erroneous statement such as this should be perpetuated and re-published.

The facts are that several other products are available for the control of bovine trypanosomiasis, including 'Samorin' and 'Novidium' (May & Baker Ltd.), 'Ethidium' and 'Prothidium' (The Boots Co. Ltd.), 'Trypanidium' (S.P.E.C.I.A.) and 'Antrycide' (I.C.I. Ltd.).

Yours faithfully,

J. P. CAVILL

Credibility of the anti-nuclear lobby

SIR,—I hope I am not too late to comment on Professor Pearce's thought-provoking contribution to the nuclear debate (20th July, p260).

●A "selective, admonishing and often haughty style" is surely more characteristic of the "anti-nuclear lobby" than of Mr Justice Parker.

●Difficult though Professor Pearce finds it to see how "any sane mortal would perpetrate false claims so as to foist an unsafe industry on an unsuspecting public", this appears to be exactly the opinion of many of the nuclear industry's critics. I also rather suspect that his remark about "the desire to be right and toe the party line" again describes an attitude more characteristic of the critics than of the industry.

●I doubt if anyone would argue that the nuclear power industry never makes

mistakes. But I would like to advance the apparently outlandish idea that the anti-nuclear lobby can make mistakes too.

●Professor Pearce's point about a possible change in the make-up of society invalidating the case for nuclear power is weak on two levels. First, what would we think of an administration which declined to build public housing, schools or hospitals, or even to reform itself, on the grounds that presently prevailing values cannot be assumed to be those of the future? Second, even if society changes world-wide in the direction the critics wish, there will still be a demand (albeit reduced) for central power stations. Is there not then a case for building nuclear plant, and allowing the dearer, dirtier and more dangerous coal and oil burners to be phased out? To forestall a possible objection, I fully agree that a community limited to near the surface of one planet cannot continue to grow indefinitely. But why the optimum level of economic activity should be just that of the developed world in 1978 has never been explained, to my satisfaction at least.

●It is certainly proper to put a case against nuclear power. But the advocates of this case are surely honour bound (as I think Professor Pearce would agree) both to examine this case themselves, and to permit others to do so. It is my distinct impression that many of the present 'antis' do neither now, and would do neither in the future in Professor Pearce's "institutions to debate and evaluate those alternatives".

●While not all the opposition to nuclear power is irrational, a great deal of it certainly is, and it is surely unfair to castigate as "hysterical outbursts" any statement to this effect.

●In the face of some of the arguments put to him, is it not understandable that Mr Justice Parker should occasionally be "perplexed and confused"? For example, reportedly one suggestion was that future energy needs should be met with "cosmic forces". This sort of talk perplexes and confuses even me, and if that makes me a haughty and unfeeling rationalist, so be it.

●Whether the debate becomes a conflict is surely in the hands of the critics as much as of the industry. The death of a demonstrator at Creys Malville in France makes this point sadly dramatic. A recent article in *New Scientist* (3 August, p349) is distinctly ominous, and I for one would welcome Professor Pearce's comments on the kind of tactics hinted at therein.

Lastly because of the tone of the "debate", I had better state that I am a physicist with no professional connection to the nuclear industry. I also hold that complete lack of bias, like perfect social justice, is an unattainable ideal. But, again like social justice, it is very much worth-while to work towards it.

Yours faithfully,

news and views

GABA and benzodiazepine receptors

from Leslie L. Iversen

MINOR tranquillisers of the benzodiazepine series (diazepam = Valium for example) are the most widely prescribed of all psychotropic drugs. The discovery last year (Squires & Braestrup *Nature* **255**, 732; 1977; Möhler & Okada *Science* **198**, 849; 1977; see *News and Views* **266**, 678; 1977) of specific high affinity binding sites for ^3H -diazepam in mammalian brain, possibly representing a novel type of 'benzodiazepine receptor', was thus an exciting breakthrough.

Previous work on this group of drugs had suggested that they might mimic or enhance the synaptic actions of the inhibitory amino acid transmitter γ -aminobutyric acid (GABA) in the brain. At first, biochemical studies failed to reveal any direct connection between benzodiazepines and GABA at the receptor level. Thus benzodiazepines did not influence the binding of ^3H -GABA to its receptor sites in brain membrane preparations, and conversely GABA and related drugs did not influence ^3H -diazepam binding. A series of recent studies, however, now suggests that some interaction may exist between the two types of receptor. Thus, Tallman *et al.* (*Nature* **274**, 383; 1978) report that GABA and the GABA-like drug muscimol cause an increase in the apparent affinity of binding sites for ^3H -diazepam in rat cortical membranes *in vitro*. This effect is blocked by the GABA antagonist bicuculline, which itself lowers the affinity of the drug receptor sites for ^3H -diazepam.

Other studies suggest that, as with enkephalins and opiate receptors, brain normally contains an endogenous ligand for the benzodiazepine sites. Thus, Karobath *et al.* (*Eur. J. Pharmacol.* **49**, 323; 1978) and Marangos *et al.* (*Life Sci.* **22**, 1893; 1978) describe the existence in acid acetone extracts of bovine brain of substance(s) (molecular weight less than 1000) which inhibit the binding of ^3H -diazepam. The specificity of these compounds, however, is not yet clear. The substance described by Karobath *et al.* for example, was present not only in brain but could be detected in even larger amounts in peripheral tissues such as heart and skeletal muscle.

A very interesting proposal has been made by Toffano *et al.* (*Proc. natn.*

Acad. Sci. U.S.A., **75**, 4024; 1978), (see also Guidotti *et al.* *Alfred Benzon Foundation Symposium GABA Neurotransmitters*, 22–25 May, 1978, Munksgaard, Copenhagen, in press; Guidotti *et al.* this issue of *Nature*, page 535), who describe the purification from rat brain of a protein which seems to act both as a ligand for benzodiazepine receptors and as a modulator of GABA receptors. They studied the binding of ^3H -GABA to synaptic membranes from rat brain *in vitro*, and confirmed what others have found (Enna & Snyder *Molec. Pharmacol.* **13**, 442; 1977; Greenlee *et al.* *Life Sci.* **22**, 1653; 1978), namely that high affinity binding of ^3H -GABA is not detectable in freshly prepared membranes but becomes evident only after the membranes have been subjected to exhaustive washing. In fresh membrane preparations only a limited amount of specific ^3H -GABA binding, with relatively low affinity ($K_d \sim 200$ nM) can be detected, whereas after repeated washing, freezing and detergent treatment specific binding increases and a high affinity component ($K_d \sim 20$ nM) is revealed. The supernatant fractions from fresh membrane preparations contained a substance which inhibited high affinity GABA binding when added to washed membranes. Chromatographic purification of this material yielded a 500-fold enrichment of a heat stable protein, with apparent molecular weight 15,000. The possible relation of this endogenous inhibitor of GABA receptors to benzodiazepine receptors stems from the observation that the purified substance is able to inhibit the binding of ^3H -diazepam when brain membranes are preincubated in its presence. Furthermore, incubation of fresh membrane preparations with quite low concentrations of various pharmacologically active benzodiazepines seems to displace the endogenous inhibitor and converts the GABA binding properties of such membranes

to the high affinity type normally seen after removal of the inhibitor protein by washing. Thus, the benzodiazepines might act normally to enhance the actions of GABA at its receptors by displacing an endogenous modulator protein which forms part of a macromolecular complex constituting the GABA receptor-ionophore.

This attractive hypothesis will certainly generate a great deal of interest and further work. It is perhaps surprising that small amounts of the endogenous GABA receptor inhibitor could be detected in non-cerebral tissues such as liver. The relevance of this mechanism to the pharmacological actions of benzodiazepines also rests critically on the correlation between the known pharmacological actions of various benzodiazepines *in vivo* and their ability to displace the endogenous modulator protein from brain membranes; so far only a limited number of such drugs have been tested.

Our understanding of the cellular localisation and molecular nature of the benzodiazepine receptors remains limited. Labelling of benzodiazepine receptors *in vivo* has been demonstrated using ^3H -flumetrazepam (Chang & Snyder *Eur. J. Pharmacol.* **48**, 213; 1978) and ^3H -diazepam (Willamson *et al.* page 533, this issue of *Nature*). The findings of Chang *et al.* (*Proc. natn. Acad. Sci. U.S.A.* in the press) suggest that these receptors are located in large part on glial cells in rat brain. They report that a variety of chemical or surgical lesions which destroy the neuronal elements in corpus striatum or cerebellum of rat brain fail to alter the density of benzodiazepine binding sites in these brain areas. Furthermore, benzodiazepine sites were enriched in subcellular fractions containing glial cells, and like Guidotti *et al.*, Chang *et al.* were able to detect high affinity benzodiazepine binding sites in membranes prepared from rat C6 glioma cells. The postulated glial localisation of benzodiazepine sites, however, is not easy to reconcile with the notion that these sites interact directly or indirectly with GABA receptors, which are thought to be located largely on neurones. The fact that ^3H -diazepam and ^3H -GABA binding sites do not show parallel distributions among brain regions in any case suggests that they are not necessarily linked—and indeed may not even occur on the same cellular elements. □

Leslie L. Iversen is Director of the MRC Unit of Neurochemical Pharmacology, Cambridge.

Anomalous cosmochronology . . .

from Stephen Moorbath and David N. Schramm

FROM the comprehensive sweep of topics at a recent conference on the use of isotopic dating in geology and cosmology*, it is clear that isotopes can shed light on almost every aspect of Earth and Planetary Sciences. Reviews ranging from their use in dating the Universe to their use in deducing the diet of our ancestors indeed provided food for thought.

There has been a revolution in our understanding of the early Solar System as a result of the discoveries of isotopic anomalies in Allende and other carbonaceous chondritic meteorites. The discoveries were led off in 1973 by Clayton and his group at the University of Chicago, who discovered that the oxygen isotopic composition had large variations which could not be explained by simple fractionation and seemed to require an admixture of a different nucleosynthetic component that that of the bulk of the Solar System material. The addition of these non-standard nucleosynthetic components was given a timescale when Typhoon Lee, D. Papanastassiou, and G. J. Wasserburg (Caltech) showed that ^{26}Al was present when objects in the Solar System solidified. Since ^{26}Al was presumably made in a supernova and ^{26}Al has a half-life of only 7×10^5 yr, this seemed to indicate that a supernova explosion had occurred within a few million years of the formation of the Solar System, and had injected freshly synthesised material into the protosolar cloud. With these observations in mind, various astrophysical theorists have developed models for forming the Solar System utilising supernova shocks and grain formation and penetration as a means of getting the anomalies from the supernova into the protosolar cloud.

New isotopic anomalies

At the Snowmass conference, observations of new isotopic anomalies both elucidated and complicated the scenario. Although most of the rocks in Allende have almost normal Solar System isotopic composition, with the exception of oxygen anomalies and excess ^{26}Mg due to the decay of ^{26}Al , it was found about a year ago that two inclusions in Allende, labelled C-1 and EK 1-4-1, were anomalous for almost every element included. In addition, the nature of the isotopic anomalies was different in each inclusion. For ex-

ample, where one particular set of neutron-rich isotopes might be enriched in EK 1-4-1, the same set is depleted in C-1. The discovery of the anomalies in these samples was made by Clayton's group, Wasserburg's group, and G. Lugmair (University of California, San Diego). New and extremely intriguing isotopic information on these two inclusions was presented. In particular, hopes for a simple explanation tying all the anomalies to one type of nucleosynthetic process were complicated by the discovery that in some mineral separates both proton-rich and neutron-rich anomalies were found, whereas in others only one or the other was present. Also, whereas C-1 seems to show more elements anomalous than normal material, it is depleted in the amount of freshly injected ^{26}Al . Since the anomalies in C-1 for the most part tend to be depletions rather than additions, this may mean that C-1 is a 'truer' sample of the protosolar material, and what we now call normal is really a well-mixed sample, including the ejecta from a supernova. Perhaps EK 1-4-1 is a sample in which the supernova ejecta is enriched relative to normal. The question of the composition of the different components which went to make up the Solar System and eventually became mixed together to yield what we call normalised isotopic composition will continue to be worked on, and there are, no doubt, going to be many new surprises.

Universality

The universal nature of the ^{26}Al chronology, and thus its significance, was strengthened considerably by new results reported by J. C. Lorin and M. C. Michel-Levy (Paris) who showed that ^{26}Al anomalies are also present in the Leoville carbonaceous chondrite, whilst J. D. MacDougall (University of California, San Diego) and D. Phinney (Johnson Space Center) showed that the carbonaceous chondrite Murchison also had ^{26}Al enrichment comparable to that in Allende. They also found that some samples of Murchison showed extremely large mass fractionation of Mg isotopes. This large mass fractionation is intriguing because the only other samples that have shown large isotopic fractionation were EK 1-4-1 and C-1.

One point which received some attention was the relation between the 10^6 -yr ^{26}Al time scale and the 10^8 -yr time scale relating the last nucleosynthetic event to produce ^{129}I and ^{244}Pu to the time when xenon daughter products of these two radioactive nuclei

were retained in meteorites. Typhoon Lee and his collaborators at Chicago showed that it may be quite possible for a supernova simultaneously to make the ^{26}Al and the neutron-rich heavy anomalies observed in EK 1-4-1 and yet not produce ^{129}I and ^{244}Pu . On the subject of ^{129}I , one point brought out by A. Zaikowski (University of California, Berkeley) was that in Allende there seem to be at least two separate periods of condensation separated by about 3.7 Myr. That is, the ^{129}I seemed to be included in some rocks 3.7 Myr before others. This shows that some material in a meteorite may be considerably more primitive than other material in that same meteorite. C. Allègre and a team at Paris are trying to utilise the different nucleochronologies and retention times from Pb, Sr, Ar and Xe to show that the time/temperature history of the early Solar System was probably not monotonic, but went through at least one secondary reheating stage for which he set some parameters, but not all.

Hints of possible new results which have not yet been substantiated, but which if true would be extremely exciting, were presented by O. Manuel (University of Missouri, Rolla) who showed that there may be a correlation of Te isotopic anomalies with the strange Xe anomalies found enhanced in some carbonaceous chondrite material by E. Anders and his group at Chicago. Another intriguing suggestion based on preliminary experimental results was that of J. L. McCrumb and his collaborators at San Diego, who suggested that it may be possible for chemical fractionation to produce non-linear isotopic effects. If true, this would have extremely important implications for interpretations of such things as the oxygen isotopic anomaly.

There was also discussion of cosmological timescales as well as the discussion of timescales in the early Solar System. It was pointed out by K. Hainebach and his collaborators that a consistent age for the Universe can be obtained, utilising not just nucleocosmochronologies, but also the traditional Hubble dynamics and globular cluster ages and big bang nucleosynthesis. The age for the Universe where all methods agree is between 13.5 and 15.5 billion yr.

Stephen Moorbath is in the Department of Geology and Mineralogy, University of Oxford and David N. Schramm is at the Enrico Fermi Institute, University of Chicago.

*The Fourth International Conference on Geochronology, Cosmochronology and Isotope Geology was held at Snowmass-at-Aspen, Colorado, August 20-25, 1978.

... and geochronological anomalies

MANY papers discussed the application of all the available age methods to igneous, metamorphic and sedimentary rocks from all over the world, ranging in age from ancient to almost modern. Finding the oldest terrestrial rocks is a fashionable and prestigious exercise. J. Barton Jr. (Witwatersrand University) obliged with gneisses from the Limpopo belt of southern Africa which yielded a rubidium-strontium whole rock isochron age of nearly 3.8 billion yr, although the uranium-lead systematics of these rocks are highly complex and gave younger ages. At the other end of the geological time scale, the controversy regarding the age of the KBS-tuff, an important marker horizon in the Plio-Pleistocene succession of Northern Kenya, continues unabated. G. H. Curtis and his collaborators (University of California) favour an age of ~ 1.8 Myr, whereas F. J. Fitch and coworkers, from the Universities of London and Cambridge, favour ~ 2.5 million years. Clearly a tuff nut to crack!

The new and exciting samarium-neodymium age method was thoroughly aired by many workers. The geochemical coherence of parent and daughter forms a sharp contrast to the rubidium-strontium and uranium-lead methods and offers the possibility of tracing crustal evolution in certain geological environments which could wholly or partly disturb rubidium-strontium and uranium-lead systematics.

Geochemistry

On the application of initial strontium, lead and neodymium isotopic ratios to petrogenetic studies of igneous rocks and of the geochemical and temporal evolution of the Earth's continental and oceanic crust, and of the upper mantle, most speakers considered that geochemical heterogeneities have existed in the upper mantle for at least 1 to 2 billion years, as judged from isotopic measurements on oceanic basalts. Another issue, still highly controversial, concerns the origin of calc-alkaline lavas (mostly andesites) at continental margins, such as the west coast of South America. Conflicting interpretations of 'anomalous' isotopic and trace-element compositions were proposed by D. E. James (Carnegie Institution, Washington) and by J. R. Lancelot and colleagues (University of Montpellier and United States Geological Survey, Denver). James favours derivation of andesites by massive subduction and partial melting of vast quantities of sediments of continental

origin, whereas Lancelot *et al.* prefer selective sialic contamination with radiogenic strontium of an essentially mantle-derived magma with low $^{87}\text{Sr}/^{86}\text{Sr}$ ratio during fractional crystallisation of the calc-alkaline liquid. This controversy is closely related to the problem of whether the continental crust grows through geological time, or whether its volume has remained essentially constant. I (S.M.) believe that the bulk of isotopic, geological, geochemical and geophysical evidence very definitely favours continental growth, but both arguments will continue for a long time yet. Nonetheless it is now certain that continental igneous rocks frequently acquire an isotopic imprint of the older continental crust through which they make their way to the surface, and this phenomenon can be used to provide constraints for the age and nature of rocks at depth which are not exposed at the surface at that particular locality. P. N. Taylor and S. Moorbath (University of Oxford) reported that the 3.7 billion yr-old sialic craton of West Greenland appears to underlie only a very small part of the voluminous, extensively exposed 2.9 billion yr-old craton. Furthermore, W. Compston and B. Chappell (Australian National Uni-

versity) believe that they have demonstrated that Precambrian continental material was present in the lower crust of southeastern Australia during the early Palaeozoic, so that crust in this region did not originate solely as new oceanic crust at that time.

On the non-radiogenic stable isotope front, the oxygen isotopes as always offer a wide range of fundamental geological applications. F. J. Longstaffe, H. P. Schwarcz and R. H. McNutt (McMaster University) have shown that up to the onset of partial melting the oxygen isotope ratios of Archaean granitoid gneisses reflect the nature of their protoliths. Fortunately, the conclusions closely parallel those drawn from radiogenic isotope studies. Furthermore, the irrepressible H. P. Taylor, Jr. (Caltech), as usual presenting as many new data as all other workers combined, showed how oxygen isotope ratios vary sympathetically with initial strontium isotope ratios in passing from west to east in the great Peninsular Ranges Batholith of Southern and Baja California, and how this must reflect an increasing crustal component in the petrogenesis of this major rock unit.

This was an important and magnificently organised conference. Those geologists who nowadays still ignore, misunderstand and disbelieve constraints imposed by isotopic and geochronological data very definitely do so at their own peril. □

Presynaptic receptors

from S. Z. Langer

THE classical picture of events at nerve endings and synapses has been modified over the past few years by accumulating evidence for the existence of presynaptic receptors for neurotransmitters, in addition to the classical postsynaptic receptors which mediate the response of the effector organ (in the periphery) or of the postsynaptic neurone (in the central nervous system). The presynaptic receptors, found on the outer surface of the nerve endings from which neurotransmitter is released, are thought to be involved in the modulation of the neurotransmitter release evoked by stimulation, by means of a negative feedback mechanism in which a neurotransmitter regulates its own release.

As U. S. von Euler (Karolinska Institute, Stockholm) pointed out in his opening lecture at the First International Symposium on Presynaptic Receptors*, the first indications of the existence of presynaptic receptors can

be traced back as far as 1957 when results on the effects of alpha-adrenoceptor blocking drugs on the stimulation-evoked release of noradrenaline from noradrenergic nerve endings triggered considerable interest (Brown & Gillespie *J. Physiol. Lond.* 138, 81; 1957). It was not until 1971, however, that the hypothesis was formulated that alpha-adrenoreceptors are present in noradrenergic nerve endings and are involved in negative feedback control of noradrenaline release. Since then evidence for presynaptic receptors in the peripheral and central nervous systems has continued to accumulate (see for reviews Langer *Biochem. Pharmacol.* 23, 1793; 1974; *Br. J. Pharmacol.* 60, 481; 1977; Starke *Rev. Physiol. Biochem. Pharmacol.* 77, 1, 1977; Westfall *Physiol. Rev.* 57, 659; 1977).

Evidence for the presynaptic location of the alpha-adrenoreceptors that regulate noradrenaline release has been found in the rat heart. In this tissue there is a significant reduction of ^3H -dihydroergocryptine binding after de-

* Held in Paris on 22-23 July, 1978

generation of the noradrenergic nerve endings induced by the administration of 6-hydroxydopamine. The loss of alpha-adrenoceptor binding sites after chemical sympathectomy indicates that some of these sites are located presynaptically on noradrenergic nerve endings.

Several contributions stressed the fact that there are differences in affinities for agonists as well as for antagonists between the postsynaptic alpha-adrenoceptors that mediate the responses of the effector organ and the presynaptic inhibitory alpha-adrenoceptors that regulate the release of noradrenaline during nerve stimulation. These differences open up the possibility that selective presynaptic agonists or antagonists could be developed to elicit pharmacological actions as a result of effects on neurotransmission. These changes in transmitter release can be brought about through the selective activation or blockade of presynaptic receptors, and might be of therapeutic importance in conditions such as hypertension, depression and schizophrenia.

In addition to the presynaptic inhibitory alpha-adrenoceptors that regulate noradrenaline release in the peripheral and the central nervous systems, presynaptic receptors involved in negative feedback mechanisms for other neurotransmitters have been reported in the peripheral and in the central nervous systems. Evidence for presynaptic inhibitory muscarinic receptors was presented for peripheral as well as for central cholinergic nerve endings. The presence of presynaptic inhibitory dopamine receptors was reported in the rabbit nucleus caudatus and also in the rat striatum. In addition, results were presented which are compatible with the presence of presynaptic inhibitory GABA receptors in the GABA-ergic nerve endings of the rat substantia nigra. It is therefore possible that in addition to the presynaptic receptor systems involved in the autoregulation of the release of noradrenaline, acetylcholine, dopamine and GABA, that presynaptic receptors for other neurotransmitters might be present in nerve endings to subserve the function of the fine regulation of transmitter release upon the arrival of nerve impulses.

In addition to the presynaptic receptors through which the neurotransmitter can regulate its own release, a real mosaic of receptors seems to be present on the noradrenergic nerve endings. Evidence was presented for several presynaptic receptors which are involved in the inhibition of noradrenaline release during nerve stimulation: the muscarinic receptor, the dopamine receptor, the prostaglandins of the E series and in some neurones, the opiate

and adenosine presynaptic inhibitory receptors. Presynaptic receptors involved in the facilitation of the stimulation-evoked release of noradrenaline include beta-adrenoceptors and also angiotensin II receptors. These presynaptic receptors can be activated by other neurotransmitters (acetylcholine) by circulating endogenous compounds (adrenaline, angiotensin II) or to locally produced substances (prostaglandin, adenosine) to modulate transmitter release.

In the central nervous system there is increasing evidence for the modulation of the release of neurotransmitters through presynaptic receptor mechanisms. In the rat cerebral cortex β -endorphin and enkephalin reduce, while GABA enhances the stimulation-evoked release of noradrenaline. In

S. Z. Langer is Director, Department of Biology, Synthelabo, Paris.

addition, the stimulation-evoked release of dopamine from dopaminergic nerve endings can be modified by acetylcholine and GABA. Another example is the inhibition by enkephalin of the potassium-evoked release of substance P. It was concluded that local neurotransmitter interactions involving presynaptic receptor systems may represent a physiological mechanism for the modulation of transmitter release in the central nervous system. Attention was drawn to the fact that presynaptic receptors can be acted on by exogenously administered agonists or antagonists to modulate the release of neurotransmitters induced by nerve impulses. The potential therapeutic relevance of this principle was discussed and it seems that presynaptic receptors in the peripheral and the central nervous system could be considered as target receptors for the development of new drugs. □

Intraplate earthquakes

from Peter J. Smith

MOST of the world's earthquakes occur in narrow bands clearly associated with plate boundaries. To say that the causes and mechanisms of such earthquakes are therefore perfectly understood would be to exaggerate, but at least it is possible to see in general terms that large-scale plate boundary could quite easily lead to violent releases of stress. But what about intraplate earthquakes, of which there is a not insignificant number? By definition there are no intraplate active oceanic ridges, subduction zones or transform faults. So what causes earthquakes away from plate boundaries?

There are several possibilities. Some intraplate earthquakes may be associated with volcanism, and some specifically oceanic shocks registering on seismographs may be due to underwater slumping. Other seismic events seem to represent slippage of local faults. Whether such faults are always as local in cause as they are in geography is another matter, however, for some have probably been left over from the time when their present localities were closely associated with plate boundaries and others may result from stresses in the interior of a plate viewed as a membrane ('membrane tectonics')—stresses that are bound to be influenced by what happens at the edge of the plate.

All three of these causes ('slumping,

fracture zone activity, and possible submarine volcanism') have been invoked in a very general way by Estill and Odegard (*Geophys. Res. Lett.* **5**, 485; 1978) to account for seismicity in the vicinity of the Hawaiian Islands. Estill and Odegard were much less concerned with causes, however, than with the fact that the Hawaiian ridge appears to be more seismically active than previously thought. They report that between July 30, 1976 and March 30, 1977 the Makapuu Ocean Bottom Seismograph, which lies 10 km off the south-east coast of Oahu, recorded no fewer than 359 local events. Most of the epicentres determined (65 in all) occurred on, and in the immediate vicinity of, Hawaii, which is understandable, although two events of $M_L > 4$ took place near Oahu and Nihoa, respectively, well away from the currently active volcanic centre.

But if Estill and Odegard have produced an observational surprise, Campbell (*Geophys. Res. Lett.* **5**, 477; 1978), who is more concerned with cause than with observation, has come up with a theoretical one. As part of a re-examination of the Charleston, South Carolina, earthquake of 1886 (*U.S. Geol. Survey Prof. Paper* 1028; 1977) Long and Champion recently showed that earthquakes in the Charleston area occur in, or very close to, a large mafic/ultramafic crustal intrusion, and Kane has pointed out that there are similar intrusions in several other seismic regions of eastern North America. This has led several people to suggest

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University.

that some local earthquakes may be caused by the stress concentrations set up by such intrusions in the felsic continental plate.

Campbell has now treated this problem (or at least a simplified version of it) analytically. He shows that a vertical intrusion of circular or elliptical cross section is likely to produce stress concentrations only 20–30% greater than the regional stress if, as most workers have assumed, the intrusion has a greater rigidity ($\times 2$ maximum) than that of the rest of the crust. In general, such a stress differential is unlikely to give rise to local seismicity. But if, as Kane suggested, the intrusion has been serpentinised, the picture is transformed. A serpentinised intrusion could have a rigidity up to 10 times lower than that of the surrounding crust, which could lead to stress differentials of up to 200%. Under these circumstances it is quite possible that

earthquakes would occur in the continental plate close to the intrusion.

Of course, it is quite evident that not all crustal intrusions give rise to earthquakes. Campbell speculates that this may be because some intrusions do not have mechanical properties sufficiently different from those of their surroundings (that is, they are not serpentinised enough); because some do not go deep enough, do not have a small enough radius of curvature, and are not oriented appropriately to the regional stress field (as demanded by the model); and because some, though not excluded by these two considerations, may nevertheless simply be too small to produce other than very low intensity events. Crustal intrusions may not account for all, or even most, intraplate earthquakes, but as a possible cause they must certainly now be added to the existing list. □

Drosophila genetics at Szeged

from Michael Ashburner and Peter Lawrence

FOR peripatetic *Drosophila* geneticists the long hot summer ended with a meeting on *Drosophila* biology at Szeged in Hungary*. Less 'molecular' than the recent conferences in Crete (see *News & Views* 275, 364; 1978) it provided an opportunity to meet many workers from Communist countries. In view of the widespread boycott of the Moscow International Genetics Congress this summer, this

opportunity was especially welcome and opened many eyes to work going on in Eastern Europe and the academic centre, Akademgorodok, in Siberia.

Bands and interbands

The problem of the relationship between the 'genes' of *Drosophila* and the bands of the polytene chromosomes, and the problem of the genetic significance of bands and interbands, continues to be a challenge as we heard in a spirited paper from I. Zhimulev of the Soviet Academy of Sciences Institute of Cytology and

Genetics in Akademgorodok. Zhimulev and his collaborators have taken a very small region of the X chromosome of *Drosophila* including the large band 10A1.2, long famous as the site of the eye colour mutant *vermilion*, and attempted to discover other genetic functions coded for by the same band. It would seem that this very large band does include the information for, in addition to *vermilion* (which codes for tryptophan pyrrolase), at least one and possibly three vital loci. All of these complementation groups seem, from deficiency mapping, to be located at the edges of the band, the bulk of whose material appears to be genetically silent.

Zhimulev is a proponent of the idea that bands do not represent structural or functional units but are, in effect, epigenetic phenomena reflecting only the state of gene activity within a tissue. In Zhimulev's view interbands are active genes, a theory suggested by others. This of course is anathema to those of us who thought that Beermann had dealt a death blow to the 'Istanbul hypothesis', for this would imply that the similarities in banding seen between the chromosomes of different tissues reflect only similarities in transcriptional activity, perhaps largely of what are called, not always with due humility, 'house-keeping' genes. To be certain there are other straws in the wind which indicate that perhaps a major re-evaluation of the problem may not be overdue: to mention but two: D. Ribbert (of the University of Münster) reported last year to the Helsinki Chromosome Conference that the banding patterns of the polytene chromosomes from two tissues of the fly *Calliphora* were completely different and now we have evidence from the gene cloners that 'identical' bands (for example in different stocks of *D. melanogaster* or in different, but related species) may differ in their base sequence, at least in part. Clearly the whole problem should be filed under 'keep a watching brief'.

Related to this subject are studies attempting to analyse genetically structures which everyone agrees are active genes—that is to say the puffs of the polytene chromosomes. Two such were discussed at Szeged—the 87A/87C 'heat shock' inducible puffs (J. Gauscz and colleagues, Szeged) and the 2B early ecdysone inducible puff (E. S. Belyaeva & Zhimulev, Akademgorodok). This difficult approach to the study of gene control in *Drosophila* has yet to bear fruit but at

Michael Ashburner is in the Department of Genetics, University of Cambridge, and Peter Lawrence is at the MRC Laboratory of Molecular Biology, Cambridge.

THE Biological Research Centre of Szeged, known as Hot Spring Harbor on account of the hot, sulphurous, local waters, was founded some 6 years ago and is the showpiece of Hungarian biology. More than 100 workers are organised into four Institutes, housed in modern and well equipped buildings. An important feature of the Centre is that for 5 years it has benefited from a large UNESCO grant, under the United Nations Development Programme, that in addition to allowing it to purchase equipment has enabled sending many of their younger scientists abroad for periods of one or two years. For example the small *Drosophila* and nematode group, under Istvan Kiss, brought together

biologists from various different fields and nearly all have, in effect, been trained during stays in the laboratories of Western Europe and North America. In many cases the close collaboration between these Hungarian scientists and their former colleagues continues and many of the papers presented at the meeting attested to the value, to both sides, of these contacts. More novel has been the programme within the BRC to train scientists from Third World countries — by scholarships many students, who would otherwise often find it difficult to receive such a training, have been brought to Hungary for quite long periods to collaborate with the Hungarian scientists.

*A Workshop on Current Topics in Insect Development was held at Szeged, Hungary on 12–15 September and hosted by the Hungarian Academy of Sciences Research Centre, Szeged. It was supported by UNESCO and the International Cell Research Organisation.

2B several lethal complementation groups have been identified and some alleles seem to show abnormalities in the normal temporal sequence of gene activities inducible by ecdysone in salivary glands. Since the 2B puff is one of the first to respond to the hormone the implications of these observations for the analysis of cascade control reactions during development are clear to see.

Ecdysone receptors

Another topic of enduring interest is that of the general control of development by ecdysone. The meeting was fascinated by accounts of two temperature-sensitive ecdysone-deficient mutants by J. Lepesent (University of Paris) and J. Holden (Queen's University, Kingston), which will be invaluable for the study of ecdysone action. Even more fundamental, however, is the problem of the ecdysone receptors. So elusive have these been that some were beginning to doubt their very existence on anything other than theoretical grounds. The breakthrough by J. D. O'Connor (University of California, Los Angeles) and by Fristrom's group in Berkeley, has now been made. What was needed was a radiolabelled analogue of ecdysone of very high biological activity and very high specific activity. This was synthesised by the tritiated reduction of the phytoecdysone stakisterone C to the very active ponasterone A. Using tissue culture cells O'Connor and his group have characterised a proteinaceous binding activity that does everything an ecdysone receptor should do, at least to those acquainted with vertebrate steroid receptors. Thus the binding shows a temperature-dependent nuclear translocation, a translocation accompanied by a change in sedimentation constant, it is saturable and shows biologically realistic affinity constants to various ecdysone analogues. Moreover derivatives of the original cell line exist which are unresponsive to the hormone and at least some of these seem to lack the receptor. The receptor's purification and localisation to ecdysone-treated salivary gland chromosomes is eagerly anticipated. If current attempts to isolate the ecdysone-responsive genes on

plasmids succeed we are in for an exciting few years.

Sex determination

R. Nöthiger and his colleagues (University of Zurich) are throwing new light on an old problem, at least as far as *Drosophila* is concerned. For years *Drosophila* geneticists have accepted the balance theory of sex determination of Bridges, whereby sex is determined by the ratio between the number of X chromosomes and autosomes, without enquiring too deeply just what this may mean in genetic or developmental terms. Nöthiger suggests that, all organisms, whether man, beast, or green things, possess a 'key gene' whose activation or inactivation is required for sexual development along one or other pathway. In different organisms different methods will be used to control the activity of this key gene: in some (the marine worm *Bonellia*) the signal will be environmental, in others genetic. In *Drosophila* it would be this key gene that responds, by an unknown mechanism, to the X chromosome:autosome balance. The report of T. Cline of Princeton University of a new locus on the X chromosome, which appears to be normally 'on' in females and 'off' in males, and may thus correspond to Nöthiger's proposed key gene, is therefore particularly exciting. Cline has found that if the normal state of affairs is disturbed by mutation, sex-limited lethality results. Nöthiger's laboratory has been systematically analysing the several mutant loci known in *Drosophila* which effect a sex reversal and it was suggested that perhaps the activity of their wild-type alleles is normally subordinate to that of the X-linked key gene.

Cell division and death

The control of cell division and cell death in growing organs remains a mystery, but *Drosophila* geneticists are making a start on its analysis. It has been known for some time that when wild-type cells are generated in a slow growing (*Minute/Minute*⁺) background they grow fast and take over much of the compartment. Morata and Ripoll (*Dev. Biol.* 42, 211; 1975) discovered that when the converse experiment is done—slow growing clones generated in a wild-type background—the weaker cells are completely eliminated. Yet compartments (or indeed whole flies) consisting entirely of *Minute* cells form normally (Ferrus & Garcia-Bellido, *Wilhelm-Roux Arch.* 183, 337; 1977). This phenomenon, termed cell competition by its discoverers, was discussed by P. Simpson (Gif-sur-Yvette) who suggested that the relative growth rate of the cells is the critical factor. *Minute* cells generated in a *Minute*

background, for example, survive. Further, starvation which reduces the total amount of growth, diminishes the effects of competition, rescuing the weaker *Minute* cells. It seems that some kind of cellular struggle which results in survival of the fittest is operating in growing cell populations.

J. Szabad (Szeged) reported results obtained in collaboration with T. Schupbach and E. Wieschaus (University of Zurich). They have made gynandromorphs of *Drosophila* larvae and studied the distribution of male and female epidermal cells. These gynandromorphs are in many respects more valuable than adult ones, as they are a more direct representation of the blastoderm. Thanks to these studies we now know that the ♂/♀ boundary line on the blastoderm is convoluted, and that segmentation coincides with blastoderm stage. For a long time the relationship between the cells on the blastoderm and the gynandromorph fate map has remained uncertain. We now know that each cell on the blastoderm is represented by about 4 sturts on the fate map.

It is always debatable whether conferences are really worth it. In the case of Szeged there can be no question that the formal discussions, and more importantly, the informal ones (especially between colleagues who, for the wrong reasons, so rarely meet) were very worth while. □

The LEP summer study

from a Correspondent

MUCH progress in understanding subnuclear constituents has been made using a new facility for probing the structure of matter at extremely small distances ($\sim 10^{-14}$ cm), namely the electron-positron storage ring. In such a machine beams of electrons and positrons collide head-on producing a single massive photon, which can then pair produce other, heavier particles. This process is quite democratic; any charged particle which exists with a mass less than the equivalent energy of one of the electron beams must be produced with a calculable cross section. Furthermore the production process is 'clean'. The pair of new particles is made alone, devoid of the debris of other subnuclear particles which is always present if the proton beam of a conventional accelerator and a fixed target is used.

The basic constituents of matter seem to be fermions, occurring in families of four, each containing two quarks and two leptons. These fermions

Erratum

In the article 'Illegitimate recombination legitimised' (*News and Views* 274, 213; 1978) the reference (column 3, page 213, line 10) to the 9-base pair repeat generated by the integration of insertion element IS4 and attributed to P. Starlinger, is incorrect. The repeated sequences generated by IS4 have not yet been determined.

interact through vector particles: the photon, charged and neutral massive vector bosons, and gluons which are responsible for the electromagnetic, weak and strong interactions, respectively. So far, experimental evidence for three families of fermions has been found: (u, d, e, ν_e) , (c, s, μ, ν_μ) , (t, b, τ, ν_τ) . Of these, the charmed quark c , the bottom quark b , the heavy lepton τ and its neutrino ν_τ , have only been discovered since 1974. The top quark t , though not yet observed, is confidently expected to be seen in the near future.

It was against the background of these exciting discoveries that some 80 particle and accelerator physicists from Europe and the United States met at the Summer School of Theoretical Physics in Les Houches, France and at CERN, Geneva from 11 to 22 September to study and discuss LEP, the proposed Large Electron Positron storage ring. The energy range of such a machine would extend from the highest energies attainable with the generation of machines now operational (PETRA at DESY, Hamburg, West Germany, see *Nature* **274**, 202; 1978) or under construction (PEP at the Stanford Linear Accelerator Center in the United States), which might be ~ 30 GeV per beam, to energies of ~ 100 GeV and above. Much new and exciting information on heavy quarks and leptons is expected from PEP and PETRA. LEP however is mainly intended to probe the world of the vector particles, in particular the massive bosons W^+ , W^- , Z^0 which we believe are responsible for the weak interaction. Weinberg and Salam have proposed a possible unification of the weak and electromagnetic interactions in which both interactions have the same strength. The observed 'weakness' of the weak interaction results from the large masses of the W^+ , W^- and Z^0 as compared with the massless photon. Such theories predict the masses of the W^+ , W^- and Z^0 from measurements of weak interaction phenomena at low energies. So far the simplest such theory, the Weinberg-Salam theory, agrees with all observed weak phenomena, and predicts masses of ~ 90 GeV for the Z^0 and ~ 80 GeV for the W^+ and W^- . Because of the direct weak coupling of Z^0 to e^+e^- (recently experimentally observed in a beautiful experiment performed at SLAC: SLAC-PUB-2148, to be published in *Physics Letters*) an increase of 10^3 – 10^4 in the rate of interactions is expected if the beams of LEP are tuned to an energy of $1/2 M_{Z^0} = 45$ GeV. W^+W^- pairs of the above mass are also expected to be produced at a reasonable rate for beam energies in LEP of ~ 100 GeV. The observation of such

effects in LEP would mean that nearly a century after the discovery of weak interaction processes, their understanding would be on the same level as quantum electrodynamics (the only exact physical theory of particle interactions we have) and we shall have reduced from four to three the fundamental forces in nature.

In the intervening two years European particle physicists, represented by ECFA (The European Committee for Future Accelerators) under the chairmanship first of G. von Dardel, of the University of Lund, and more recently by M. Vivargent of LAPP, Annecy, have expressed a strong preference for such a large e^+e^- storage ring as the next major European high energy physics facility. During the same period a detailed design study of such a machine has been made (CERN/ISR-LEP/78-17). This design was the basis of the discussions at Les Houches. The storage ring is larger than any existing or planned accelerator, with a radius of 3.5 km. The estimated construction cost of ~ 1000 million Swiss francs is however somewhat less than that of the recently completed CERN SPS proton accelerator. In a preliminary time scale outlined by J. Adams, Executive Director General of CERN, the machine might become operational by about 1988, some 12 years after the start-up of the SPS. The construction of the machine within such a time scale seems possible without significant increase of the current CERN budget of some 600 million Swiss francs per annum provided some existing CERN facilities, by then becoming obsolete, were closed.

Much time was spent at the meeting on alternative 'scenarios' to the simple one described above. What if there were so many neutrinos coupling to the Z^0 that the width is much wider than the 3 GeV now expected? (a suggestion by J. Ellis, CERN). The answer seemed to be that floods of new charged heavy leptons must be seen at LEP. Some theorists (for example M. Veltman of the University of Utrecht) are already looking to even higher energies of more than 300 GeV, where effects of direct $Z^0W^+W^-$ coupling should become discernable. At this energy the currently quite mysterious mass spectrum of the quarks and heavy leptons should become considerably clearer. This is the world of the Higgs scalar boson which in the Weinberg-Salam theory is required to be an observable particle, but of unspecified mass. There were hints that the effects of gluons, the intermediaries of the strong interaction, should be seen particularly clearly in virtual $\gamma\gamma$ collisions, a process with a copious rate at LEP energies. Thus quarks and gluons could

one day possibly be liberated in the laboratory. In his concluding speech S. L. Glashow of Harvard University presented a dazzling catalogue of these alternative scenarios; a cornucopia of subnuclear riches. There have never been stronger arguments for building an accelerator before, and none has been as eagerly awaited as LEP. In the words of the motto chosen by the participants on their last evening at Les Houches, LEP's do it! $\square$

Breeding more protein

from B. J. Mifflin

Now you see it, now you don't. The protein gap much discussed in the late 1960s was largely abolished, at least on paper, by the lower protein recommendations of the 1973 FAO/WHO committee. Subsequently increased controversy has raged between those who argue that there is still a protein gap and those who protest that only calories are lacking. In many respects the arguments are futile and do little for those who have insufficient food which is of poor quality. The FAO/IAEA took a more positive position when in 1968 they organised a meeting to set up a co-operative programme with the GSF to improve the nutritional value of the grains of cereals and food legumes by supporting research programmes in a number of developing countries aimed at modifying protein and amino acid content. This September they convened a conference* to assess the results of the 8 years of the programme and review the present state of knowledge.

The continuing deficiency of adequate nutrition was emphasised in the opening talk by R. Bressani (Instituto de Nutricion de Centro America y Panama, Guatemala City). His results show that by up-grading the protein quality of cereal seed diets, either by using high lysine maize, or by adding legume seed supplements, food intake is increased, infant mortality reduced and the acreage required to provide sufficient protein considerably diminished. Since World Bank estimates indicate that more than a third of the world's population suffers from serious malnutrition the original aims of the programme still seem relevant and

* Organised by the Joint FAO/IAEA Division of Atomic Energy in Food and Agriculture of the International Atomic Energy Agency (IAEA) and the Gesellschaft für Strahlen- und Umweltforschung (GSF) at Neuherberg, near Munich in the Federal Republic of Germany, on 4–8 September, 1978.

worthwhile; the remainder of the conference was chiefly concerned with reporting progress towards achieving those aims.

In the basic sciences considerable advances have been made. The major protein components of seeds are the storage proteins present in protein bodies. These are deficient in lysine in cereals and in sulphur amino acids in legumes. Although there are considerable differences between the storage proteins of legumes and cereals, in both cases they seem to consist of polymorphic families of related polypeptides. In maize, wheat and barley the putative structural genes have been located on various chromosomes and some mapping carried out. Success with *in vitro* synthesis of legumes and cereal storage proteins has been achieved in a number of laboratories and some mRNA has been isolated and cDNA prepared and cloned. These studies should provide a better understanding of the basic mechanisms of protein accumulation in seeds and offer the potential for use of genetic engineering techniques; some of these techniques were discussed in the context of future programmes.

Both as a direct result of the FAO/IAEA programme as well as of studies funded by other agencies, high lysine genes have been found in maize, barley, sorghum and possibly wheat and millet. The current status of the genes in the first three crops was reviewed. Although some progress has been made in understanding the nature of these mutations by determining their chromosome location little is yet known about their biochemical basis other than that the synthesis of the storage proteins is depressed. More information is required as to which of these genes offers the possibility of providing both high quality and high yield. So far the most promising breeding work seems to have been done in sorghum in which yield is not greatly affected, since the smaller size of the high lysine grains is balanced by increased seed number. Very promising results were also reported from CIMMYT, where the use of various modifying backgrounds have led to greatly improved *opaque₂* lines of maize. Although some success has been made with the *Hipoly* gene in barley the lysine content of the lines seems to decrease as yields improve. Besides having normal yields new lysine varieties also have to be accepted by the consumers and meet the normal agronomic requirements, such as disease resistance. Although these criteria have not all been met it must be realised that plant breeding takes a long time and it is necessary to be patient. Some idea of the patience required was demonstrated by the

results of the Nebraska programme of high protein wheat breeding which had been in progress for 20 years before the release of the first variety in the US. This variety, which is now finding acceptance on the basis of its general properties, combines increased protein content and high yield.

In legumes the problems are more concerned with yield and protein quality than with protein content. In a critical and forceful talk H. K. Jain (Indian Agricultural Research Institute, New Delhi) pointed out the large amount of selection pressure and breeding that had been exerted on the cereals in comparison with the legumes. Legumes are not poor in total biological yield but insufficient of it is recovered in the harvested seed. Considerable success has been achieved through mutation breeding and recurrent selection programmes in obtaining improved ideotypes of several legumes with a much better harvest index. As regards protein quality, the problem is to improve the amino acid spectrum of the seed protein as well as to decrease the content of the various adverse nutritional factors present in legume seeds.

The conference ended with a review of the technological aspects of plant use and the role plant breeding and

biochemistry has played and must continue to play. Implicit in this must be an increased realisation that weight of produce alone is not enough and that a direct measure of productivity involves an assessment of the quality of the produce and the uses to which it can be put. When the work reported is viewed as a whole it represents a considerable success particularly in the time frame normally required to bring about stable genetic change and to select improved varieties of crop plants. It is therefore particularly disappointing that this programme is not being renewed with increased funding but, at best, will only continue in a limited way with funds from the Governments of the Federal Republics of Germany and of Sweden. Despite the fact that man's major necessity is food, all of which is ultimately derived from plants, the Plant Sciences remain amongst the Cinderellas, poorly funded and unfashionable. The FAO/IAEA programme has shown what can be done with a fraction of the funds spent on such grandiose technological playthings as supersonic travel. □

B. J. Mifflin is Head of the Biochemistry Department, Rothamsted Experimental Station.

A hundred years ago

M. BOUILLAUD, the once celebrated medical practitioner, who is a member of the Paris Academy of Science, assailed M. du Moncel in the sitting of September 30, and asserted that the phonograph and microphone experiments must be the work of ventiloquists. This fit of incredulity was occasioned by the recital of experiments made with the singing conductors. M. du Moncel asked for a commission of investigation to be appointed, although such accusations are not deserving of any notice, and have, indeed, raised universal ridicule. But the regulations of the Academy forbid any commission to be appointed to pronounce on the works or communications of members. Another curious scene took place at the sitting of last Monday. M. du Moncel presented to his colleagues, the "condensateur chantant," which had been

exhibited on the previous Saturday. He retired to the room of the Académie Française, in company with M. Faye, closed the door and sang. His voice was heard coming from a number of sheets of paper, in which six sheets of tinfoil had been inserted, and connected with the wires of an induction coil. M. Bouillaud was obliged to retreat from the position he had taken at the sitting of September 30. He made no allusion to the accusation of ventiloquism, but read a long quotation from Descartes, to show that "even if a speaking machine had been constructed, it could by no means be considered as a thinking machine." He said that speaking was not only a mechanical action, but also an intellectual work, so that neither the phonograph nor the singing condenser could be regarded by any means as really speaking! The whole assembly, in spite of its usual gravity, burst into roars of laughter. M. Milne-Edwards, who spoke at the previous sitting, said with much propriety, he should not have answered M. Bouillaud if he had understood such was his issue. Unfortunately he had understood, as everybody in the assembly did, that M. Bouillaud questioned the honesty of the experimenter.

review article

Exploration of the continental basement by seismic reflection profiling

Jack Oliver

Department of Geological Sciences, Cornell University, Ithaca, New York 14853

The structure of the continental crust and uppermost mantle is being explored with higher resolution than previously attained through application of the seismic reflection profiling technique of the petroleum industry. Crustal structure is diverse, and features such as faults, unconformities, magma bodies, and the crust–mantle boundary have been delineated.

SOME four billion people derive their livelihood from this planet, so society's need for a thorough understanding of the Earth and a comprehensive inventory of potentially accessible Earth resources seems obvious. Yet except for mining prospects and districts, and the sedimentary basins that are the habitat of petroleum, there is little detailed or direct knowledge of subsurface Earth structure and composition at depths greater than a few tens or hundreds of metres. In most areas, deep rocks of the crystalline basement can be described only in general terms based on indirect evidence. Their genesis and evolution remain largely unknown.

The reasons for this remarkable state of affairs are partly economic and partly historical and organisational. They are also partly technological although there are means for improving substantially, if not ideally, our knowledge of the crystalline basement. Better mapping and improved field and laboratory studies of surface rocks, drilling for informational purposes, study of xenoliths of basement origin, and further application of a variety of geophysical methods are all feasible and promising. The article focuses on potentially the most productive and the most sophisticated geophysical technique—seismic reflection profiling—and its application to studies of the basement. This does not mean that other methods are not valuable; in general, they provide complementary information. The seismic reflection profiling technique discussed here should not be confused with the seismic refraction technique that is conventionally used for exploration of the crust, or with the Russian DSS method, which uses both refraction and wide-angle reflections.

During 1976 world expenditure on seismic reflection profiling was well over one billion dollars. Essentially all of this money was spent on exploration for petroleum. Continuing effort on this scale by the petroleum industry has resulted in, and is the result of, development of the technique of echo ranging in the Earth to a very high level of sophistication. In recent years, the industry has produced such innovations as non-explosive sources, digital field recording for movable listening arrays of thousands of detectors, computer processing of immense quantities of digital data, and powerful new methods of analysis and interpretation that have greatly enhanced understanding of the stratigraphy and structure of sedimentary basins. Modern reflection profiling bears little resemblance to the simple one shot—one detector method initially employed in the 1920s.

Within the past few years in several different countries, successful attempts have been made to apply these modern

techniques, with appropriate modifications, to exploration of the continental basement and hence greater depths (for a review see ref. 1). Here, the term 'basement' refers to crystalline rocks typically lying below the sedimentary veneer that is some 0–10 km thick. The continental basement rocks of interest here extend through the base of the crust at some 35–45 km and into the underlying mantle to depths of 50 or so km, the current limit of the method. Although rocks of the deep continental basement have been explored with some success previously using various geophysical techniques, the new efforts based on reflection profiling offer far greater resolution of structural detail and much better information on other properties that are currently unknown or poorly known. Because of the potential of this much improved, yet rarely applied, observational capability in seismology, the potential of other geophysical and geological methods, the great extent of the basement, and the direct and informative relation of the deep continental basement to the near-surface rocks, the continental basement must be considered one of the major scientific frontiers of modern geology.

The method

The principle of the seismic reflection profiling technique is deceptively simple. A disturbance at or near the surface of the Earth generates elastic waves that propagate through the Earth and are detected and recorded by sensors at the surface near the source. Although other kinds of waves are sometimes useful, most information comes from the compressional waves that travel along near-vertical paths and are partially reflected at buried sub-horizontal interfaces between rocks of contrasting impedance. The travel time of a pulse propagating along such a path is perhaps the prime information gathered, but the amplitude, phase, frequency content, and apparent surface velocity of the signal are also valuable.

The source and receivers are moved together along a line and the experiment repeated at closely spaced intervals so that subsurface reflecting horizons may be traced, and a profile or section obtained in a similar manner to that of a marine echo sounder. The basic travel-time data must be ultimately converted to depths and reflectors properly positioned; hence it is necessary to know or to measure the spatial distribution of velocities along the profile. One common method for velocity measurements uses reflected waves travelling along paths that are somewhat off the vertical. Thus, a single source might be detected and recorded by many sensors distributed over

distances ranging from near zero to significant fractions of the depth of the deepest reflecting horizon.

Furthermore, because the sources generate kinds of waves (surface waves, shear waves, waves with complex paths, diffracted waves) in addition to the nearly vertical travelling compressional waves that are normally the signal, arrays of many source elements and arrays of many receivers are commonly used to discriminate against the unwanted waves as well as background noise. Some data are also collected off the line, to permit the waves propagating out of the plane of the section to be identified.

In practice, there are numerous variations of the technique which depend on a large number of factors, such as local terrain, local propagation phenomena, economics, available hardware, characteristics of the particular target, and noise conditions.

As an example, a field procedure sometimes used in the COCORP project is described in some detail in the following. (COCORP is consortium for continental reflection profiling, and the project is the major US effort to apply the seismic reflection profiling technique of the petroleum industry to study of the deep basement of the continents. The procedure represents a compromise among various factors including acquisition of maximum possible information, economics, and logistics.)

COCORP uses the VIBROSEIS technique developed by the Continental Oil Company. Instead of an impulse generator such as an explosion, weight drop, or compressed air gun, a truck-mounted vibrator serves as a source element. Each vibrator imparts a peak vertical force of some 13 tons over about 20 ft² of the Earth's surface; the force is near-sinusoidal in time but of slowly varying frequency. The signal thus resembles a radar 'chirp' in character, though not in frequency. Typically the duration of vibration is 20 s, and the frequency varies linearly from 8 to 32 Hz over the interval. Cross correlation of the recorded signal with the input produces a record resembling that from an impulsive source, subject, of course, to restrictions of bandwidth and other properties of the VIBROSEIS source and the propagation. The advantages of the method include flexible and precise control of source character, elimination of drilling to implant explosives, avoidance of legal restrictions on explosives and the explosive hazard, and efficient coupling of source energy into elastic waves without great loss through rupture or other non-linear effects near the source. VIBROSEIS has been used widely and successfully on land by the petroleum industry for many years.

In a typical COCORP survey, stations in the field are spaced at 100-m intervals. Five vibrators operate synchronously 16 times at equally spaced intervals between stations, and the resulting signals are appropriately summed. Thus, 80 sweeps are injected into the earth per station interval and combined to form a source array 100 m long.

The receiving array includes 96 stations and is thus almost 10 km long. At each station a small spread of about 30 detectors, spaced to discriminate against natural and source-generated noise, is summed and recorded as one of 96 channels. Once the 80 sweeps at one station are recorded, the sources and the 3,000-element listening array are, in effect, moved 100 m along the line and the entire process repeated. Thus, along a line a few tens of kilometres in length, information travelling along tens of millions of rays is used in the analysis, a high level of redundancy that can be very advantageous. The data are recorded digitally in a form that will accommodate a very large dynamic range.

A further advantage is gained by computer processing the data. A wide variety and large number of methods including frequency and wavelength filtering, construction of synthetic seismograms, proper spatial positioning (migration), beam-forming, and various signal enhancement techniques are commonly applied depending on the particular problem. One powerful method, called common depth (or common reflection) point stacking, is based on combination of data from rays incident upon a particular reflection point at slightly different angles. Under favourable conditions signals are much enhanced.

COCORP typically uses 12, 24 or 48-fold common depth point stacking. In the sense that information from segments of many rays passing through a common zone is combined, the method resembles X-ray tomography.

Although seismic reflection data appear in other useful forms such as velocity profiles and contour maps, the end product is typically a section with distance as the abscissa and travel time, or depth, as the ordinate. For the casual observation, and to a first approximation, this may be thought of as a section through the Earth. It is misleading to carry this view too far, however. A detailed interpretation of the data requires an understanding of wave propagation, field procedures and data processing, and a knowledge of related geological and geophysical data for the area. This report is too brief to present detailed analysis or interpretation of data. Instead two sections are shown and described in general terms, and some conclusions based on studies to date are presented after a discussion of current efforts to explore the continental basement. (For a more detailed description of seismic reflection profiling techniques and interpretation as found in the petroleum industry see refs 2-5.)

Seismic exploration of the continental basement

A proper strategy for exploring a major frontier of the Earth sciences must include a judicious blend of several factors including the nature, scope and scale of the scientific problems, capability of the method, economics, expertise of personnel, and logistics. In an effort to achieve this blend, the COCORP project operates as follows. Many scientists from industry (largely the petroleum industry), government agencies, and universities participate in committees to advise on technical, scientific, and administrative problems. Cornell University acts as the operator or prime contractor. The field work is conducted by large geophysical contracting companies. Data are processed through routine stages, and available at modest cost, so that further specialised processing and interpretation are facilitated.

The choice and nature of sites for such surveying are critical. Six sites have been surveyed to date in the US. The first site in Hardeman County, Texas, was selected for favourable seismic and field conditions in initial testing of the method, and with little regard for the geology. Later sites, two in the Rio Grande Rift near Socorro, New Mexico, one crossing the boundary fault of the Wind River Mountains in Wyoming, one across the Franciscan basement-continental basement boundary in the Great Valley of California, and one across the San Andreas fault in California, were selected because of geological problems of special interest. A recognised problem of regional or crustal scale, as opposed to local or surficial scale, is found at each of these sites. Typically, a few lines of reflection profiling totalling some tens of kilometres have been carried out at each site. In all cases the results have been highly encouraging. In the longer term, however, it is planned that longer lines traversing the entire continent will be explored, so that problems of still larger scale will also be investigated. Applying this method of exploration to studying the modern basement is so new, and the region to be studied so vast and varied, that one must anticipate a period of rapid learning and development in the early stages of the project.

Two examples of the data

Figures 1 and 2 show two sections obtained by the methods described above for the locations in the Rio Grande Rift area^{6,7} indicated by 1 and 2A in Fig. 3. The reproductions do not do justice to the original data but some of the major features can be seen. The abscissa for Figs 1 and 2 is the distance in kilometres times 10; the ordinate is two-way travel time. Multiply by three to convert time to approximate depth in kilometres.

In Fig. 1, the upper 1-1.5 s of data for the western two-thirds of the profile show nearly horizontally stratified sediments of the rift valley. The sediments are broken into horsts and grabens by normal faults. It is only this portion of the section that would be

Fig. 1 Seismic section for line 1, Rio Grande Rift (see Fig. 3).

studied in normal petroleum exploration, and in much greater detail. Below these sediments is the crystalline basement which outcrops east of the bounding fault as seen at about station 180. Some shallow Palaeozoic sediments that overlap the basement at the eastern end of the section are indicated by events at <1 s.

Principal interest here is in information from greater depths. In some areas of the section, such as from ~ 1 to 3 s and between stations 10 and 75, there is a paucity of reflected data as indicated by the lack of short horizontal lineups. The rocks of such zones must be relatively free of acoustic heterogeneities. In this same range of times near the centre of the section are some horizons that dip to the west and may be faults. To the east (right) are additional basement structures.

Beneath the bounding fault through most of the record there is a zone lacking in reflected energy, possibly because of intrusives associated with the boundary. To the east (right) considerable structure in the basement is apparent, and at ~ 12 s there is a strong reflector that, based on time, corresponds to the top of the mantle. This reflector cannot be traced across the entire section, although it might be correlated with reflectors to the west at about the same time.

There is little reflected energy on this section at times greater than 12 s. At the western end of the profile there is a strong reflection at 7 s with an associated diffraction. This event corresponds to a horizon identified as the top of a magma body by Sanford⁸. Other profiles in the Rift show additional evidence for this mid-crustal body of molten rock. (For more detailed discussion of these data, see ref. 7).

Figure 2 shows a section for line 2A (Fig. 3) that begins slightly south of line 1 and continues southwards. Some of the major features are (1) the sediments showing much less structure than

is the case for line 1 because line 2A is more nearly parallel to the geological structure, (2) a transparent zone in the upper basement between the base of the sediments and almost 4 s; (3) a strong reflector corresponding to the magma body at about 7 s and dipping to the north; and (4) a zone of reflected energy between about 11 and 12 s presumably corresponding to the top of the mantle.

The above qualitative and cursory descriptions obscure the great potential for obtaining more quantitative information by careful study, computer modelling, and other forms of analysis, but they provide a first impression of the type of data now available on the crust and illustrate the much improved resolution and vast potential of the technique.

Although seismic reflection profiling of the deep continental basement is relatively new, and only a tiny fraction of the basement has been surveyed at present, some conclusions can be drawn, although they must be held subject to revision as more data are acquired. The following points are based largely on COCORP experience, but they are compatible with similar observations elsewhere (see ref. 1 for a review and citations)^{6,7,9-13,16}.

(1) The continental basement at any particular site some tens of kilometres in dimension is typically heterogeneous on the scale of less than one or a few kilometres. Reflections from within the basement are only infrequently continuous for more than a few kilometres. Diffractions, reflection character, and transparent zones further attest to this heterogeneity. While layered models such as the classical but already outdated granite-basalt crust or

Fig. 2 Seismic section for line 2A, Rio Grande Rift (Fig. 3) for coordinates.

Fig. 3 Map of section of Rio Grande Rift in New Mexico showing locations of seismic lines. Solid lines 1 and 2 indicate locations where data for Figs 1 and 2 were taken. Dotted lines 1A, 2A, 3 and 4 show other lines that were surveyed but not discussed in this paper.

those based on seismic refraction data may be useful for interpretation of some seismic data, they can only be approximations in a gross sense to the geology of the crust. The deep crust seems to be, not surprisingly, like rocks with a history at depth but which are now at the surface (see also ref. 14).

(2) On a larger scale, there is great variation from site to site in the character of the seismic reflection profiles; consequently such variation must exist in the basement geology. With the exception of some features of the seismic profiles in the Rio Grande Rift, many of which show the magma body at a depth of about 18–20 km and some consistency at Moho depths, there is little similarity and great difference in seismic sections from one site to another. In Hardeman County strong diffractors are found in a quantity not observed elsewhere, and there are also shallow basement reflectors of unusual length of continuity, at least 17 km. The San Andreas fault in California shows up as a series of diffractors to depths of ~10 km, while deep reflectors are discontinuous across the fault zone. In the Wind River Mountain area the major thrust can apparently be traced to depths of almost 25 km. Many other deep reflectors corresponding to faults or other horizons may be seen. The Great Valley line shows fewest deep reflectors, perhaps because the Franciscan basement is so badly deformed. At any rate, there is little similarity from one site to another and ample evidence for de-emphasising universal models of the continental crust. It follows therefore, that a wealth of new knowledge of the structure of the crust must be available using the reflection technique.

(3) There is no evidence for a single consistent mid-crustal reflecting horizon corresponding to the Conrad discontinuity, a term that should probably be abandoned.

(4) In existing data the Mohorovicic discontinuity does not generally appear as a single simple reflector. Instead there is commonly a band of reflected energy. A possible interpretation is the laminated sort of boundary proposed by Meissner¹⁵ and perhaps suggested by exposures of the lower crust–upper mantle in the Ivrea zone.

(5) With the abundant evidence from geology and geophysics indicating heterogeneity throughout the crust, it would be remarkable if the mantle directly below the crust were homogeneous.

(6) At particular sites the method reveals features of the basement that, in nature, are geological (as opposed to geophysical) such as active magma bodies, faults, unconformities, folds, intrusions, and perhaps brecciated zones, as well as boundaries between rocks of different acoustical impedances. Detailed discussions of such sites can be found elsewhere^{9–13,16}.

(7) Continued application of the seismic reflection profiling technique including modern developments should provide a wealth of new knowledge and lead to a much enhanced understanding of the continental basement, a major frontier of modern earth science.

The results from the COCORP project depend on numerous participants from universities, government laboratories, and industry. This research was supported by the NSF.

Effects of intense stratospheric ionisation events

G. C. Reid & J. R. McAfee

Aeronomy Laboratory, National Oceanic and Atmospheric Administration, Boulder, Colorado 80303

P. J. Crutzen

National Center for Atmospheric Research, Boulder, Colorado 80303

High levels of ionising radiation in the Earth's stratosphere will lead to increased concentrations of nitrogen oxides and decreased concentrations of ozone. Changes in the surface environment will include an increased level of biologically harmful UV radiation, caused by the ozone depletion, and a decreased level of visible solar radiation, due to the presence of major enhancements in the stratospheric concentration of nitrogen dioxide. These changes are studied quantitatively, using the passage of the Solar System through a supernova remnant shell as an example. Some of the potential environmental changes are a substantial global cooling, abnormally dry conditions, a reduction in global photosynthesis and a large increase in the flux of atmospheric fixed nitrogen to the surface of the Earth. Such events might have been the cause of mass extinctions in the distant past.

It has been proposed that¹ the observed correlation between extinctions of certain species of marine microorganisms (radiolaria and foraminifera) and geomagnetic polarity reversals could be explained by the occurrence of intense solar flares. Energetic solar protons ionise the Earth's stratosphere, producing nitrogen oxides as a by-product, and thereby depleting the ozone layer that shields the surface of the Earth from lethal solar UV radiation². At present the geomagnetic field confines the direct effects of solar protons to latitudes higher than about 60°, but during the brief periods of weakening or disappearance of the field accompanying a polarity reversal the global effect would be considerably more severe.

The history of life on Earth has been punctuated by widespread and apparently sudden (on the geological time scale) extinctions affecting both terrestrial and marine animals³. Examples of such massive extinctions, each involving a significant proportion of all species existing at the time, occurred at several of the major geological boundaries. The best known is probably the terminal Cretaceous extinction, which occurred about 65 Myr ago, but the fossil record has revealed several other extinction events of comparable severity, and suggests that

they have occurred at approximate intervals of 10⁸ yr. Various mechanisms have been proposed to account for these extinctions, including climatic changes, increasing ecological competition from newly evolving species, changes in sea level, disease epidemics, poisoning by volcanic emissions, increased radiation levels from nearby supernova explosions, and several others. None has proved entirely satisfactory, however, and it seems natural to ask whether the solar-flare mechanism proposed to account for the minor extinctions associated with geomagnetic polarity reversals could also account for these much more catastrophic and massive extinctions that have tended to mark many of the major boundaries of the geological record.

Solar flares

Reid *et al.*¹ discussed principally the increased UV dose received at the surface of the Earth as a consequence of the depletion of stratospheric ozone associated with hypothetical intense solar flares. Their calculations indicated that a solar flare 100 times more intense than that of August 1972 (the most energetic observed over the 20-yr period for which observations exist) would cause a global ozone depletion of about 50% and would increase the biologically effective UV dose received at the Equator by a factor of about 2.5, assuming that the flare occurred during the 10³–10⁴ yr duration of a geomagnetic polarity reversal. Although such an event would have serious enough consequences for living organisms, there is a second environmental effect that was mentioned only briefly. This is the reduction in solar radiation reaching the surface of the Earth in the visible part of the spectrum due to absorption by stratospheric NO₂, whose absorption cross section reaches a peak value of 6 × 10⁻¹⁹ cm² near 400 nm wavelength⁴. NO₂ is formed principally by the ozone-destroying reaction

and absorption of solar visible radiation provides a routine method of measuring the NO₂ content of the atmosphere^{5,6}. The calculations mentioned above indicated that the vertical NO₂ column content would become as large as 6 × 10¹⁶ cm⁻² during

daytime conditions several months after a solar flare 100 times more intense than that of August 1972. The consequent decrease in solar radiation reaching the surface at 400 nm wavelength for an overhead Sun would be about 3.5%, increasing to 7% for a solar zenith angle of 60°. The effect on the integrated solar radiation at the surface would be offset to some extent by the accompanying increase in UV radiation resulting from the destruction of ozone, but significant changes in the Earth's radiation budget, with accompanying changes in lower-atmosphere circulation, could be expected.

As with all suggested mechanisms, however, there remains a large element of speculation that is difficult to remove. Our knowledge of the flare mechanism itself is not sufficient to say whether energetic-particle fluxes 100 times more intense than those of August 1972 can ever be expected, even once in 10^8 yr, or whether there is some absolute limit beyond which a flare cannot go. Given the occasional occurrence of such super-flares, the hypothetical climate change runs up against the problem that the residence time of flare-associated NO_x in the stratosphere is only a few years, probably not long enough to allow the enormous heat reservoir in the oceans to adjust to the new conditions and produce a true climatic change.

Supernova explosions

The degree of speculation is reduced if we consider nearby supernova explosions as a cause of intense stratospheric ionisation instead of solar flares. The suggestion that mass extinctions could have been caused by supernova outbursts is an old one, and was revived by Terry and Tucker⁷, who discussed the potential radiation hazards of such an event. Since then, other consequences of nearby supernova explosions have been suggested. Russell and Tucker⁸ specifically raised the possibility of a climatic change associated with such an event in connection with the terminal Cretaceous extinctions, though without discussing any mechanism. Ruderman⁹ and Whitten *et al.*¹⁰ discussed the depletion of stratospheric ozone expected from nearby supernova explosions, and Hunt¹¹ has recently estimated the surface temperature change caused by this depletion.

Clark *et al.*¹² have suggested that a supernova is likely to occur within 10 pc of the Solar System approximately once in 10^8 yr during passage through one of the spiral arms of the galaxy. At a distance of 10 pc, the Solar System would probably lie within the supernova remnant (SNR) shell for a period of several hundreds of years. There is growing evidence that SNRs are the source of galactic cosmic rays¹³ and that the cosmic rays are accelerated continuously during the lifetime of the SNR. This point of view is

consistent with indirect evidence from the radio emission of SNRs that they contain a cloud of cosmic-ray particles with a total energy of the order of 10^{50} erg, leading to a cosmic-ray flux of the order of 100–1,000 times the present background level.

Model of stratospheric photochemistry

We have used a one-dimensional time-dependent model of stratospheric photochemistry¹⁴ to study the effect of such enormously increased cosmic-ray fluxes on the total solar radiation penetrating the stratosphere. The model calculations were started with initial conditions corresponding to global average present-day conditions, and with all photochemical mechanisms appropriate to a latitude of 30°. The enhanced cosmic-ray fluxes began abruptly on 1 January, and were kept at a constant level for the duration of the calculation, which was taken as 5 yr.

Figure 1 shows the annual average values of total vertical ozone column content for cosmic-ray fluxes 100 and 1,000 times the present value, and indicates that a steady state has been reached after about 5 yr. Total ozone depletions amount to 64% and 89%, respectively, and are considerably larger than those calculated by Whitten *et al.*¹⁰ The differences apparently arise from differences in the model parameters, and in particular in the vertical eddy-diffusion profiles. All model calculations can only be approximate for such major perturbations, however, as it is impossible to estimate the effect of major compositional changes on transport coefficients. Figure 2 shows the corresponding values of NO_2 vertical column content, again indicating a near approach to a steady state after 5 yr, with increases from the present level of $4 \times 10^{15} \text{ cm}^{-2}$ by factors of 13 and 130, respectively.

Fig. 2 Vertical column content of NO_2 as a function of time after the onset of enhanced cosmic-ray fluxes.

Fig. 1 Vertical column content of ozone as a function of time after the onset of enhanced cosmic-ray fluxes.

Figure 3 shows the annual average steady-state height profiles of O_3 and NO_2 concentration for present-day conditions and for the same two cases of enhanced cosmic-ray flux. Concentrations below 10 km have been omitted because the appropriate tropospheric and surface sources are unknown; their effect on the stratospheric concentrations is negligible. The major depletions of O_3 and enhancements of NO_2 occur in the lower stratosphere, where the photochemical lifetime of ozone is long, and where cosmic-ray ionisation peaks. For the case of a 1,000-fold increase in cosmic-ray flux, the NO_2 concentration approaches that of ozone near 20 km.

As mentioned above, the model calculations are carried out for 30° latitude conditions, and can be taken to represent a global average. In estimating the effects at latitudes other than 30°, we assume that the stratospheric composition is the same everywhere. This assumption would, of course, be invalid if we

Fig. 3 Vertical altitude profiles of O_3 and NO_2 for present conditions (1) and for enhanced cosmic-ray fluxes (100 and 1,000).

were concerned with absolute values, but it allows us to estimate approximately departures from normal conditions. Figure 4a and b shows the spectral distribution of direct solar radiation penetrating the stratosphere throughout one year for latitudes of 0° and 60° , respectively. The solid curves represent present-day conditions, and the broken curves refer to steady-state (that is 5 yr after onset) conditions for the case of a 1,000-fold cosmic-ray enhancement. Modifications to the spectrum occur in three distinct spectral regions: the annual solar radiation is increased in the near UV, at wavelengths shorter than 325 nm,

Fig. 4 a, Direct solar radiation penetrating the stratosphere at the Equator integrated over one year (solid curve, present-day conditions; broken curve, steady-state conditions for a 1,000-fold cosmic-ray enhancement). b, Same as (a) for latitude 60° .

due to the decreased absorption in the Hartley and Huggins bands of ozone; blue and green visible radiation (325–570 nm) is substantially decreased, due to the increased absorption by NO_2 ; longer wavelength visible radiation is slightly increased, due to the decreased absorption in the Chappuis bands of ozone. The net environmental effects are (1) an increase in the biologically effective dose received by living organisms at the surface; and (2) an appreciable decrease in the total integrated solar radiation available for heating the lower atmosphere and the surface.
